It has been frequently remarked, that no disease presents itself to the physician under more varied aspects, nor offers greater difficulties for diagnosis, than aneurism; it is desirable, therefore, while studying it, that we should employ every method of investigation we possess likely to throw light upon the subject. It is in this and similar obscure conditions that we naturally look to those modern instruments which are supposed to give precision to clinical observations, and ask, What can they do for us, and how can they advance our knowledge of the condition under discussion? As an instrument especially devoted to the investigation of conditions of the circulation, the sphygmograph has been called upon, in the diagnosis of aneurism, to remove all difficulties from our path, and to demonstrate with scientific accuracy the presence and position of the aneurismal sac. When the ever-varying conditions of the circulation in health and the innumerable modifications introduced by disease, are considered, surprise cannot be felt that the mere resultant of unknown and numerous forces—for as such the pulse may be regarded—does not afford sufficient data from which to calculate the character of each force concerned in its production.

The sphygmograph gives increased facilities for observations on the blood-stream; but, until the causes of its varying indications are well ascertained, the deductions drawn from them must necessarily be fallacious. Those, then, who attempted to make use of it without previously ascertaining these, blamed the instrument for their mistakes, rather than their own want of experience.

Some years ago, I attempted to give some account of the results obtainable by the sphygmograph in the diagnosis of aneurism.† The question, however, is one of so much importance, that I feel justified in returning to it and stating the results of further experience. In thus confining myself to the consideration of a single symptom, let

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

† "The Physiology and Clinical Use of the Sphygmograph". *Medical Times and Gazette*, Nos. 9 and 10, 1873.

it not be thought that I regard it as more important than others; but, in this age of detail, when so much labour is spent on perfecting our knowledge of what may be regarded as minor points, one need not go far to find a precedent or excuse for that which must appear tedious and irksome, although perhaps necessary. While the most perfect physician may least depend on instrumental aids, nevertheless, to attain perfection, we cannot neglect the means of educating our senses which such aids afford us; then, if we have used them aright, we shall carry our sphygmographs in our finger-tips and our thermometers in our palms.

In a case of aneurism, the pulse may present certain characters which are recognisable by the finger; and, before applying to the sphygmograph for their explanation, it will be well to enumerate them.

1. *Delay* may occur in one or both radial arteries; it is of most value when limited to one, so that, on comparison of the two radials, the pulse can be detected in one preceding that in the other; if it exist in both, the impulse of the heart, or the first sound, will be found to occur an unduly long time before the pulse can be felt at the wrist. In either of these conditions, the pulse is said to be *delayed* in reaching the wrist by its passage through the aneurismal sac.

2. *Diminution in Volume*.—The pulse in one radial may appear much smaller than that in the other, or indeed altogether absent. This is usually wrongly ascribed to partial or complete obstruction of the vessel by clot in the aneurism, or occasionally to pressure of the sac upon the subclavian; these, however, are not the true causes of this phenomenon, as we shall see hereafter.

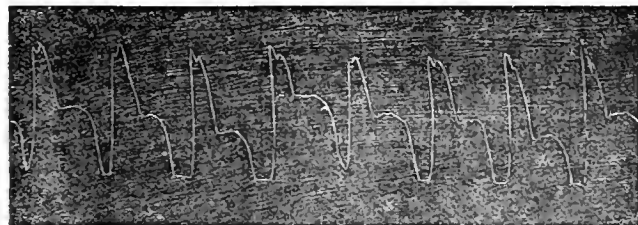

3. *Diminution in Force*.—That is, the pulse conveys a less sudden and forcible impulse to the finger than the normal pulse. It does not, however, necessarily mean a diminution of actual lifting power, but merely of the suddenness of the sensation imparted to the finger.

4. *Persistency*.—This character, the most important and perhaps the most difficult to recognise and estimate of any possessed by the pulse, refers to the amount of permanent distension of the vessel. Normally, the artery should not be perceptible to the finger except at the moment of pulsation; under certain conditions, however, the artery can be felt constantly distended, giving the well-known cord-like sensation to the finger; this permanent distension of the vessel gives the character of *persistency* to the pulse, and is the indication and gauge of arterial tension.

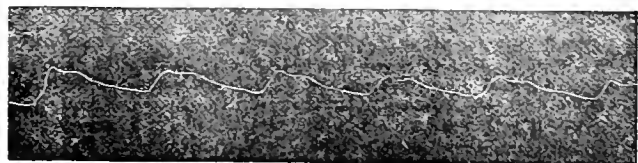

5. *Thrill* might perhaps also be considered a character imparted to the pulse by aneurism; under some rare and not very clearly defined circumstances, the pulse imparts a sensation of thrill to the finger. This probably occurs when the entrance to the aneurismal sac is very narrow, and the aneurism directly in the course of the vessel. It appears also to be occasionally produced by the rigidity of the wall of the vessel, or sometimes by a partially detached fragment of clot vibrating in the blood-stream.

If a sphygmographic tracing obtained from a case of aneurism be examined, the peculiarities of the pulse can readily be recognised. Fig. 1 shows the effect of an aneurismal sac introduced into an artificial circulation, and fig. 11 is a very typical specimen of effect of an aneurism on the human radial. The tracings in fig. 1 were obtained from a straight elastic tube ten feet long and three-tenths of an inch diameter. The heart was represented by the ball of a Higginson's

FIGURE I.—Experimental Tracings. To show Effect of Aneurism directly in the course of the Blood-stream. From Straight Tube 10 feet long, 7-10th inch in diameter, and 3 feet from valve.

1. Normal Trace from Straight Tube, without Aneurism.

2. Trace from same, with Aneurism introduced six inches from Valve.

syringe, contracted by the hand; the sphygmograph was applied to the tube three feet from the valve, and the first tracing in fig. 1 was obtained. An oval elastic two-ounce bag was then introduced, six inches from the aortic valve, to represent an aneurism directly in the course of the vessel, and the second tracing was obtained. If the tracings from the vessels interfered with by the natural and artificial aneurism be compared, the effect produced in each will be seen to be very similar. Taking each point separately, they may be enumerated as follows:

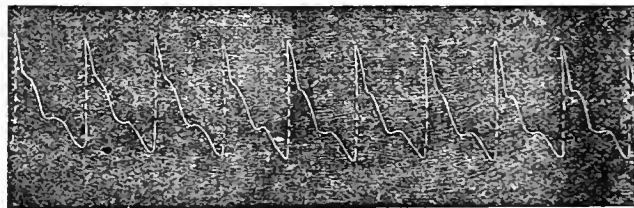

1. A sloping upstroke, which gives to the finger the character of *delay*; that is, the maximum distension, which causes the sensation of pulsation in the vessel, is not attained as quickly as in the normal; the pulse is, therefore, felt later on this side than on the other.

2. *Diminished Volume of Wave*.—The upstroke is much reduced in height; this is due to the smaller quantity of blood which forms the chief pulse-wave, a large amount of the wave being spent on the distension of the sac, which may be regarded as a kind of reservoir. It receives the great volume of blood during systole, and is partially emptied during diastole, by the continued flow of the blood-stream down the vessel, which is kept more permanently distended than by the passage of one large and more sudden wave. This gives the character to the pulse of *persistency*, the vessel being kept constantly moderately distended, a condition which cannot be recognised by the sphygmograph.

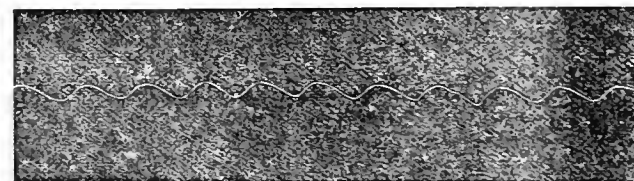

3. *Impairment of Percussion*.—The percussion-wave is entirely obliterated in these tracings, owing to the whole of the shock of the contraction of the heart being expended on the distension of the sac, which acts as a buffer.

4. *Obliteration of the Secondary Waves*.—It has just been remarked that the percussion-wave is lost, so also is the dicrotic; the downstroke, therefore, may be absolutely unbroken, as in fig. 11. These

FIGURE 11.—Axiillary Aneurism; showing Typical Effect of Aneurism on Pulse-wave. Pressure, 2 ounces.

1. Left: fairly normal; shows a little Hypertrophy of Heart.

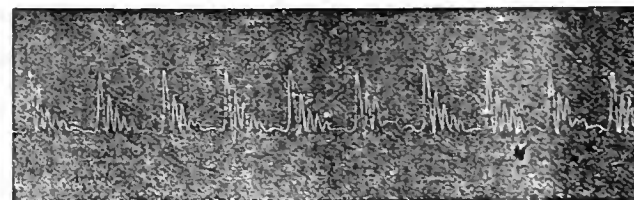

2. Right. Extremely Aneurismal in character.

small secondary waves are, like the primary wave, more or less lost in the distension of the sac.

5. *Vibratile waves* or thrill may be present. These are seen in fig. 111 to an exaggerated degree, produced in an artificial circulation

FIGURE 111.—Typical Vibratile Movements, occurring in Schema of rather non-elastic Tubing.

formed of rather rigid tubing. Some small secondary vibratile waves of this character are occasionally present in tracings from cases of aneurism; the causes said to give rise to these vibrations have already been stated.

6. A different pressure from that employed on the normal side may be required to obtain the most perfect tracings from an aneurismal pulse; it may be either increased or decreased, according to the size and persistency of the stream.

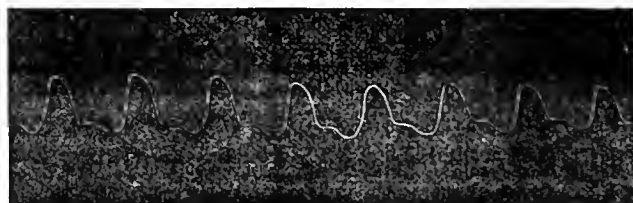

If, now, all these characters be considered, the general result to the finger is diminution, or perhaps actual disappearance, of the pulse on the affected side. This, however, does not necessarily mean any diminution of the actual amount of blood passing; it is only that its pulsatile character is diminished, and that it tends to become a continuous stream; it is, indeed, exactly the same effect as that produced on a pulse-wave by its transmission through a considerable length of elastic tubing.

It must not be thought so great a change in the pulse-wave as that seen in fig. 11 is always produced on the pulse by the presence of an aneurism. It only occurs when the aneurism is directly in the course of the blood-current, and on one of the large vessels, or involving their origin, but not when it is confined to the aorta itself. When the aneurism is one of the aorta, it only slightly modifies the pulse-tracing; it may not affect it at all. It is possible to obtain from a patient with a very large aneurismal sac connected with the aorta an almost perfectly normal pulse-trace at both wrists. In by far the larger number of cases, however, some signs will be discovered in one or both wrists; the most common are—a slightly sloping upstroke, a rounding of the apex of the tracing, and an obliteration or diminished sharpness of the secondary waves. The diagnosis of the seat of the aneurism will depend on the presence of these signs in both or one or other radial tracings. Fig. 14 somewhat imperfectly represents the effect of an

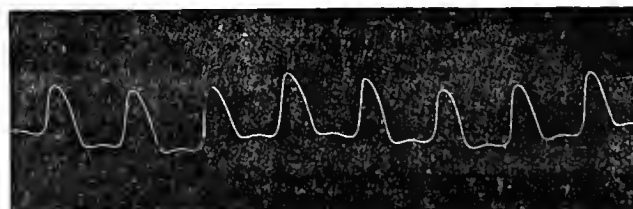

tained (fig. 14), although, be it observed, the sac was not directly in the course of the blood-stream from which the tracing was obtained. On account of the absence of other branches, the effect produced by the aneurism is greater than would be that of a sac in similar relation to the aorta. In the third tracing in this figure, the effect of distal ligation is seen; this practically reduces the aneurism to one confined to the main tube from which the traces were obtained, and imparts the aneurismal character to the pulsations much more strongly than before. The fourth tracing was obtained after a ligature had been placed between the aneurism and the main tube, cutting it off entirely from the blood-stream; the tracing immediately returns to the normal type.

Illustrations may now be given of the indications afforded by a comparison of the tracings of the two radials in cases of aneurism in different parts of the aorta. In aneurisms of the first or ascending part of the arch, both radials must be affected in a similar manner, if any effect be produced by the aneurism upon them. It is in this position, however, that the sphygmograph teaches us least, for scarcely any deviation from the normal is observable in many such cases. Fig. 5 was

FIGURE 5.—Aneurism of Ascending Part of Arch of Aorta, affecting the Flow through the Radials (Mr. Holmes).

1. Right. Pressure, 3 ounces. Presents well marked signs of Aneurism; sloping Upstroke; prolonged Tidal Wave; much Diastolic.

2. Left. Pressure, 1 ounce. Also well marked signs of Aneurism. Both pulses indicate very low tension (the patient's temperature was 99.8), and also an undulation in the base-line, due to blood-tension, varying with respiration.

obtained from a patient under the care of Mr. Holmes with a large aneurism of the ascending arch; the tracings are much alike at both wrists, but in each signs of aneurism are present, the upstrokes being slightly oblique and the apices rounded.

If the right pulse present more marked signs of aneurism than the left, the disease affects the innominate and arch. If the aneurism do not involve the aorta itself, but is confined to the innominate or subclavian, the left pulse will be perfectly normal and show no indications of aneurism, while the right will be very markedly aneurismal; as a rule, though not without exceptions, the further from the aorta or the smaller the vessel affected, the greater the change in

FIGURE 6.—Aneurism of Innominate Artery; pure; not involving Arch of Aorta or Subclavian.

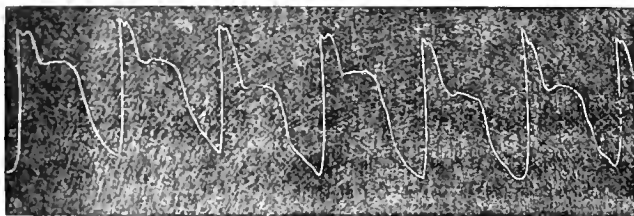

1. Right. Pressure, 4 ounces. Requires greater pressure to fully develop it.

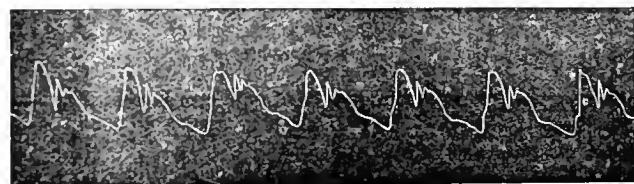

2. Right. Pressure, 7 ounces. Fully developed and highly Aneurismal.

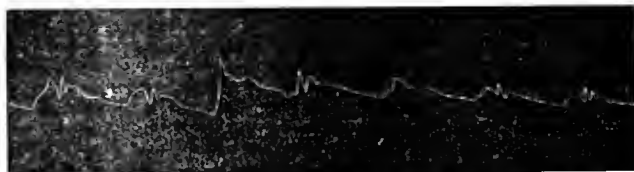

FIGURE 14.—Pulse-tracing from the Right Radial Artery, showing Effect of Aneurism not directly in the course of the blood-current. From Straight Tube 10 feet long, 3/16th inch in diameter, and 1 foot from valve.

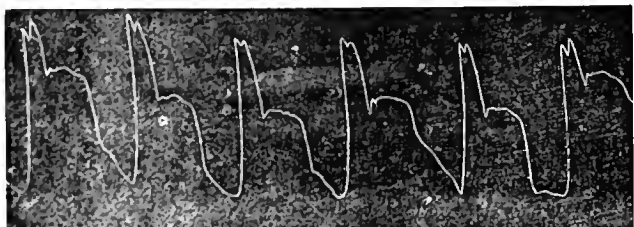

1. From Straight Tube without Aneurism.

2. Aneurism on Collateral Branch, allowing flow through it.

3. Aneurism on Collateral Branch; no flow beyond it, as if from Ligature beyond Aneurism. Distal Ligature.

4. Ligature applied between Aneurism and Main Stream: Proximal Ligature.

aneurism of the aorta upon the pulse-tracing; it was obtained from the same apparatus as before, but, instead of the aneurism being directly in the course of the blood-stream, a T-shaped piece of tubing was introduced six inches from the valve, and to the long arm of this the bag representing the aneurism was attached; the water was permitted to flow through the sac and some tubing beyond it, which thus formed a branch from the main blood-stream. A great modification is seen in the tracing now ob-

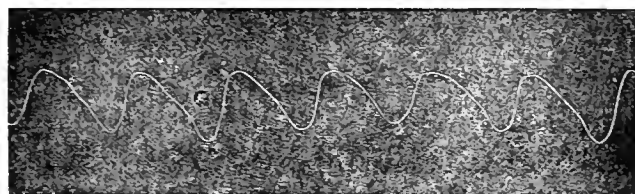

the pulse. Fig. VI, obtained from a patient under the care of Dr. Habershon, shows the effect of an aneurism, entirely confined to the innominate, on the pulse. In this case, the aorta was quite unaffected;

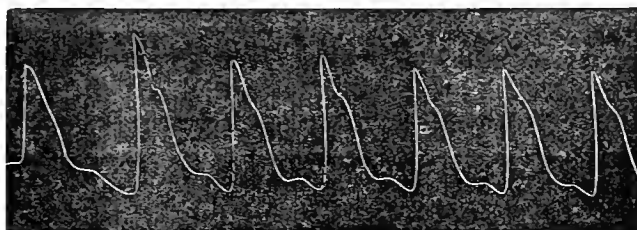

3. Left. Pressure, 4 ounces. Fairly normal.

the left pulse is, therefore, perfectly normal, while the right is highly aneurismal. The percussion-wave, well marked in the left, is entirely absent from the right, and the diastolic is also less distinct. These tracings, showing the freedom of the aorta from disease, were of the highest value from a diagnostic point of view, especially with regard to the treatment to be recommended. Fig. VII, obtained from a patient

FIGURE VII.—Aneurism of Right Subclavian Artery in Second Part (Mr. Gant). Typical Aneurismal Tracing.

2. Left. Pressure, 5 ounces. Tracing characteristic of Aortic Regurgitation and Hypertrophy of Left Ventricle.

under the care of Mr. Gant, suffering from an aneurism of the second part of the right axillary artery, illustrates a still more aneurismal form of pulse; while the left pulse has no sign of aneurism about it, although it indicates aortic regurgitation and hypertrophy of the heart, both of which were confirmed by physical signs. This freedom of the left pulse from aneurismal characters often proves of great value in diagnosis; such, for instance, was the case illustrated by fig. VIII, that of a

FIGURE VIII.—Aneurism of Right Common Carotid Artery, involving Innominate (?), the Arch of Aorta remaining free (?) (Dr. Edmunds).

1. Right. Pressure, 12 ounces. This pulse is much smaller than the left, and presents Aneurismal Characters—i.e., diminution in all the waves.

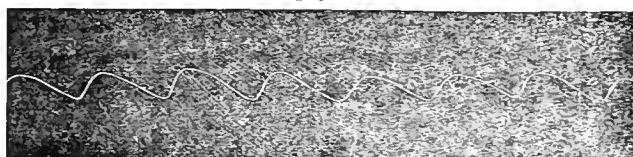

2. Left. Pressure, 7 ounces. Quite consistent with a fairly healthy heart and aorta.

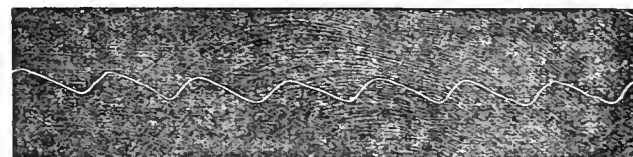

patient under the care of Dr. Edmunds, who kindly permitted me to examine her. It was a case apparently of aneurism of the right common carotid, for which Dr. Edmunds performed distal ligation of that vessel; the tracings, however, indicate, from the aneurismal character of the right pulse, that the innominate was also involved, though probably not to any great extent; while the fairly normal left pulse was a sign of the comparative freedom of the aorta from aneurismal disease—a point of the utmost importance in the prognosis and treatment of the case. This right pulse lost nearly all its aneurismal characters after the successful ligation of the carotid and apparent temporary cure of the aneurism; seven months subsequently, however, when she was again examined, the left pulse exhibited more marked aneurismal characters than the right, indicating the extension of the disease to the aorta itself. Of this case, we shall doubtless hear more from Dr. Edmunds, who has kindly permitted me to use it so far, to illustrate this sphygmographic point of diagnosis.

In some very rare cases, both pulses may be extremely aneurismal from the presence of a very large aneurism affecting all the vessels taking origin from the transverse arch. Such a case I believe that to be which is illustrated by fig. IX. These tracings were obtained from

FIGURE IX.—Very Large Aneurism of Transverse Arch, involving both Innominate and Left Subclavian Arteries (Dr. Douglas Powell and Mr. C. Heath). Both Radial Pulses highly Aneurismal.

1. Right. Pressure, 1 ounce.

2. Left. Pressure, 2 ounces. There was the most feeble pulsation in the Left Radial Artery, which required more pressure to develop it.

a patient under the care of Dr. Douglas Powell and Mr. Christopher Heath. Both pulses are in the highest degree aneurismal; to the finger, the pulse appeared almost absent: it could just be discovered in the right, but in the left was only detected with the greatest difficulty. It would naturally give an idea that the vessels were obstructed by clot; but, from the excellent tracings obtainable with the sphygmograph, it is most probable that there was no deficiency of blood passing down them: it had only lost in a great measure its highly pulsatile character owing to the presence of the large sac. The pulse had first diminished on the left side; and, as the aneurismal tumour was also first observable below the left clavicle, doubtless the aneurism commenced on the left side of the transverse arch, and gradually extended towards the right until it finally involved the innominate. Probably, at some future time, more light will be thrown on this case, and the present account may have to be modified; the very exceptional character of the tracings, however, induce me to introduce them.

[To be continued.]

## CASES ILLUSTRATING THE FAMILY HISTORY OF SYPHILIS: WITH REMARKS.

By ROBERT J. LEE, M.A., M.D. Cantab., F.R.C.P.,

Assistant-Physician to the Hospital for Children, Great Ormond Street.

IN order to determine the question of the certainty or probability of syphilis being communicated, in the event of marriage, to the mother and children, we require two series of cases, one of which, by affording certain data of a positive, the other by giving those of a negative character, will help us to arrive at the desired result. If we have a sufficient number of instances of family syphilis—that is to say, cases where the father has been infected previous to marriage, and the wife and children have exhibited symptoms of the disease more or less clearly marked—we may be able to decide, in any other particular case, the probability of such an occurrence. And, if we have a sufficient number of instances of the husband having suffered, but without any symptoms showing themselves in the

wife or children, we may also be enabled to decide of immunity being probable for the mother and children.

It is evident that we must be acquainted with all the facts which relate to the attack of syphilis from which the father suffered, the most important of which would be the interval of time between infection and marriage, the symptoms which characterised the various stages of the disease, and the condition of health at the time of marriage. This applies equally to the second series of cases—those of immunity in the family.

This method of finding a solution of the difficulties which surround the subject of hereditary syphilis appears to me, and must have suggested itself to many, as sufficiently reasonable to justify its trial, whatever labour may be required to obtain the data above stated.

The readiness with which the members of the British Medical Association respond to a request for information on any subject of professional interest, leads me to think that many who are engaged in family practice will be able and willing to communicate instances of family immunity amongst their patients, and thus assist in the collection of examples of the second series. The first series would more easily be obtained from the sources from which I have been able to collect the subjoined cases; viz., the out-patient department of a children's hospital.

There is no doubt that considerable trouble, time, and patience are necessary for the method here indicated of treating the subject of hereditary syphilis, as appears clearly from the careful collection of cases published by Mr. Hutchinson in the last number of the *British and Foreign Medico-Chirurgical Review*. But, as the questions involved are of great practical importance, and as I am inclined to think, from my own observations, that many interesting facts will present themselves, I have ventured to depart from the custom of introducing the subject at one of our societies, in preference for the more exact information to be derived from written details.

It appears to be possible to predict within certain limits the form which syphilis will assume in an infant or young child when the stage of the disease in the father at the time of conception is known; and, *vice versa*, there are certain syphilitic symptoms in the child which indicate certain conditions pre-existent in the father. That is to say, there is this difference between syphilis and zymotic diseases: that the child does not necessarily pass through a constant series of symptoms, but that, between the most severe form of the disease and the least distinct, there are certain forms which are related to the particular state of the parent or parents. Thus we perceive an indication of the existence of a period of immunity for the child, and the possibility of deciding in any particular case of the certainty, probability, or improbability of transmission.

But the great value which attaches to carefully collected cases, and the respect which I entertain for the exercise of independent reason, lead me to conclude without further remarks at present in this communication to the JOURNAL.

The parents in the following cases have given their personal histories.

CASE I.—M., aged 41, has been married three years. Four months before marriage, he had a chancre, and was under the care of Mr. De Méric at the Royal Free Hospital. He was soon cured of the primary sore. At the time of marriage, he was suffering from well marked secondary symptoms. Since recovery, and at the present time, he is in good health.—F., aged 22, suffered from severe secondary symptoms very soon after marriage, and, nine months ago, the throat was sore.—The first child was born dead and decomposed; the second is one year and eight months old. At the age of four months, a syphilitic eruption appeared, and it suffered from "snuffles". Now it has several large funiculi on the nates, one of which has been opened. The wound healed under mercurial treatment in four weeks.

CASE II.—M., aged 28, has been married five years. Five months before marriage, he had a primary sore, followed by buboes, which were discharging at the time of marriage. Subsequently, he had eruptions and secondary symptoms, such as sore-throat, etc. He is now in good health.—F., aged 24, had a primary sore one week after marriage, and buboes.—The first child was born at the eighth month, and lived five hours; the second is three years old. It was under my care at the Children's Hospital for congenital syphilis. It is now alive and well, though occasionally subject to discharges from the nose and mouth. The third is five months old. It was brought to the hospital when four weeks old with snuffles and syphilitic erythema.

CASE III.—M., aged 30, married between four and five years, had a primary sore between two and three years before marriage, which was healed in three weeks, and since then there have been no constitutional symptoms. He was treated simply with "black wash".—F., aged 28, suffered from sore-throat shortly before the birth of the first child, and has occasionally suffered since; but is otherwise in good

health.—The first child was born prematurely and dead; the second was under treatment at the Hospital for Diseases of the Skin in Blackfriars Road for syphilis, which appeared six weeks after birth, exactly as in the third child. The third, aged six weeks, is suffering from the ordinary symptoms of infantile syphilis in a mild form.

CASE IV.—M., aged 39, has been married ten years. Two years before marriage, he had a primary sore, which very soon healed. Twelve months afterwards, there were sore-throat and general weakness, from which he suffered at the time of marriage.—F., aged 34, has sore-throat slightly at times, but no well marked syphilitic symptoms.—The first child lived one week; the second three weeks; the third four years; and the fourth six weeks. The fifth was suffering from slight general symptoms of syphilis six weeks ago. Under mercurial treatment, they have disappeared.

CASE V.—M., aged 30, has been married one year and ten months. About seven years ago, he had a primary sore, which healed under treatment with "black wash" in six weeks, and, in three months, all symptoms had disappeared.—The wife has shown no signs of infection.—The child was brought at the age of three months to the hospital. There were general defective nutrition and some small superficial specific ulcers round the labia. Under mercurial treatment, the child soon appeared healthy.

CASE VI.—M., aged 38, married seven years, had a primary sore five years before marriage. He was treated with black wash, and took mercury. The gums were affected; the teeth decayed; and the hair fell off during the following three years. The skin has not been affected. His constitutional health is naturally more than usually robust. At the present time, this patient is under treatment for obstinate specific ulceration of the tongue.—F., aged 35, has no distinct history of secondary symptoms. She has severe periosteal inflammation of the left arm and synovitis of the elbow.—The first and second children died soon after birth. The third and fourth are alive and well. The fifth was brought to the hospital at the age of fifteen months with syphilitic funiculi on the nates and thighs. It was an eight months' child, and showed specific symptoms after measles. They soon yielded to mercurial treatment. The sixth child, aged four months, also showed symptoms of syphilis when ten weeks old, which were treated in the same manner as in the fifth child, and soon disappeared.

CASE VII.—M., aged 25, married two years and a half, nine months before marriage had an urethral chancre, and was treated for syphilis with "black wash". The symptoms soon disappeared, but returned three months later, when he went to a hospital, and, since he was discharged, has had no symptoms.—F., aged 27, suffered from local ulcerations three months after marriage; and, at the time of confinement, the skin and throat were much affected.—The first child was under treatment at the Children's Hospital, and died of syphilis, aged fourteen weeks; the second showed symptoms of the disease when six weeks old in a cutaneous eruption of the arms and legs, and was under treatment at the same hospital for ten weeks, when the symptoms disappeared. The parents and child regained apparently perfect health.

CASE VIII.—M., aged 20, has been married twelve months. He was infected twelve months before that, and, by medical advice, was allowed to marry. He had suffered from chancre, sore-throat, and constitutional weakness; but, at the time of marriage, was in good health.—F., aged 18, had local sores soon after marriage, and severe secondary symptoms.—The child was born nine months after marriage, and came under notice when three months old with general syphilis. It died between two and three months later, though every attention was given it.

CASE IX.—M., a healthy man, has married a widow aged 33. Her first husband had syphilis: the details are not ascertainable.—F., married fifteen years ago to her first husband, had four children.—The first was born dead; the second lived three months; the third and fourth were born dead. After remaining a widow between four and five years, she married again. It is seven years since the birth of the last child by the first husband, and the first child by the second is now fourteen weeks old. It presents well marked syphilitic dermatitis of the face, and has snuffles.

CASE X.—M., aged 28, has been married five years and a half. Between three and four years before marriage, he had a primary sore followed by buboes; but had no constitutional symptoms at any time.—F., aged 31, was constitutionally delicate. There is no account of syphilis till two years ago, when warty growths appeared on the labia, and there was erythema of the skin of the face.—The first child died at four, and was under the care of Dr. Cheadle at the Children's Hospital for congenital syphilis; the second lived three weeks; the third died at birth; the fourth was under my care at the age of three months for syphilis, and died subsequently of whooping-cough.

CASE XI.—M., aged 28, has been married four years. Between eighteen months and two years before marriage, he had a primary sore and urethral discharge, which healed under treatment in three months. No constitutional symptoms followed.—F., aged 22, has suffered since marriage from general debility; but no distinct symptoms of syphilis have shown themselves.—The first child, at the age of four weeks, exhibited well marked syphilitic symptoms, nasal discharge and snuffling, superficial cracks round the nose and mouth, slight coppery tinge of the skin, and spots on the abdomen.

### CASE OF PLEURITIC EFFUSION: PARACENTESIS THREE TIMES: DEATH: NECROPSY.\*

By W. MAKEIG JONES, M.R.C.S. Eng.,  
Late House-Surgeon to the Rotherham Hospital.

FOR permission to report the following case I am indebted to Mr. B. Walker, Surgeon to the Rotherham Hospital.

G. M., aged 30, male, unmarried, was a tall fine made man, and had served nine years in the Indian army. He had enjoyed good health till three months ago, when he had an attack of acute pleurisy. Not recovering from this, and being in poor circumstances, he came under my care as an out-patient, and was attended at his own home.

On May 27th, 1877, when I first saw him, he was lying on his back in bed, nearly exhausted, and almost cyanotic. His respirations were very frequent, and he had a constant short hacking cough. His finger nails were clubbed. His tongue was foul, and he gave a history of profuse night sweats for some time past. On examining his chest, the right side measured eighteen inches, and was superresonant on percussion. The cardiac impulse was to the right of the right nipple line. The left side measured twenty-one inches, was absolutely dull on percussion, and no breathing sounds could be heard. The chest-wall on the left was so swollen and oedematous, that it was impossible to feel the ribs. Knowing what was the matter with him, I had taken the aspirator with me, and at once proceeded to tap him somewhere about the angle of the scapula. I used a large needle, but, although the chest-wall was so oedematous, the fluid withdrawn was clear serum. It measured thirty-five ounces. The upper portion of the lung expanded at once, and the heart's apex moved close to the right of the sternum. On the next day, a succussion-splash could easily be obtained, but this soon cleared off, and he nearly recovered and was able to walk about. In about a fortnight's time, however, it began to fill again; and, on June 19th, 1877, he was in much the same state as when I first saw him. I again tapped him, and this time drew off one hundred and forty ounces of clear serum. The cardiac impulse returned to its normal site, but the lung appeared to expand very slightly. He recovered in a few days, and used to walk out; but, on July 18th, 1877, I had again to tap him, drawing off forty ounces of clear dark serum. The cardiac impulse again returned to its normal site, but no breathing sounds whatever could be heard over the left lung. On visiting him the next day, he had gone out for a walk. On July 26th, 1877, he was seized with vomiting, and his urine was nearly suppressed. It was of a high specific gravity, acid, but contained no albumen. Symptoms of uremia soon developed, he became comatose, and died on August 3rd, 1877.

A necropsy was made on August 4th, 1877, when both kidneys were found on section intensely congested, the smaller vessels in both portions standing out as dark lines; the other abdominal organs were healthy. On opening the chest, the heart was seen lying in the right side of the thorax with its apex under the right nipple line. The tricuspid and mitral valves were covered with recent lymph. The apex of the right lung was tuberculous. The left pleural cavity contained several pints of clear serum. There were a few long stringy adhesions in some parts. The costal pleura was slightly thickened where the puncture had been made, but was otherwise apparently healthy. The whole of the left lung was compressed into a carnified mass about the size of the palm of a hand. Its pleura was covered with about a quarter of an inch thickness of tough leathery lymph, which must have prevented the lung from expanding. The head was not allowed to be opened.

REMARKS.—There are two points worthy of notice in this case. 1. Although the left side of the chest was oedematous, the fluid was not purulent. 2. If, after the first tapping, iodine had been injected or a drainage-tube inserted, the patient might have recovered. Either would have been useless after the subsequent tapping, as the lung was then incapable of expansion.

\* Read before the Sheffield Medico-Chirurgical Society.

### DISARTICULATION AT THE HIP.

By T. F. CHAVASSE, M.B. Edin.,  
Assistant-Surgeon to the General Hospital, Birmingham.

THE BRITISH MEDICAL JOURNAL for April 27th contains the report of a discussion which has recently taken place, at the French Academy of Medicine, upon amputation at the hip-joint, the subject being introduced by a paper of M. Verneuil. In that communication, the eminent Parisian surgeon advocates driving back into the general circulation, by means of Esmarch's bandage, the blood contained in the limbs; and says that the operation itself should be performed by means of lateral flaps, a tedious dissection being undertaken as though removing a tumour, and all the blood-vessels ligatured before division. By these means, it is thought to procure a nearly bloodless operation, and, by facilitating the after-drainage of the wound, to render blood-poisoning less likely to occur.

What I conceive to be the best method of preventing hæmorrhage in this operation is compression of the aorta, not by the tourniquet, but by folded towels, or a pincushion, placed over the vessel, and a strong India-rubber band encircling the abdomen. Previously to this application, three or four turns with the elastic bandage should be made at the upper part of the sound thigh, to prevent egress of the contained blood until all is finished; thus constituting a sort of reservoir in the limb. On the affected side, if the operation be for malignant disease, it is better merely to elevate, and to allow the blood to gravitate, than to thoroughly empty the limb by the bandage. The blood contained should certainly not be driven out of both limbs, or, from the excessive engorgement of the internal viscera thus caused, the brain and lungs amongst the rest, unlooked for complications may arise for which the anæsthetic may be blamed.

By following M. Verneuil's particular method of operating, I must confess I cannot see any advantage to be gained. By a dexterous manipulator, the operation generally in vogue amongst English surgeons, viz., by transfixion, can be accomplished in from ten to thirty seconds, and a few minutes will suffice for securing all the important vessels. M. Verneuil's plan occupies at least half an hour, and so probably the danger from shock is increased. Mr. Spence, who, in this particular operation, has had more experience than falls to the lot of most surgeons, having performed twelve disarticulations at the hip with five successes, one of them being a primary for a machinery accident, remarks, in his *Lectures on Surgery*, vol. ii (second edition): "I have no hesitation in saying that, from my own experience, rapidity of execution in this operation is of great importance, as diminishing the risk from shock and loss of blood."

Ligaturing each vessel before it is cut, to prevent loss of blood, is unnecessary; for, in Mr. Spence's last case, at which I had the pleasure of assisting him, the operation was performed, as a last resource, upon a man with a very large malignant sarcoma of the femur; the veins of the limb were dilated to thrice their natural size. By compressing the aorta with a pincushion and India-rubber band, not more than two ounces of blood were lost altogether. The bleeding that did occur was nearly all from the large femoral vein, which had not been securely enough ligatured before the compress was removed.

Upon reference, I find that M. Verneuil advocated his operation at the Academy upon the strength of one successful case in which it had been performed. The plan of dressing that this surgeon recommends (*à la Lister modifié*) is not of the highest importance, as, by cutting the posterior flap carefully from without inwards, the edge of the wound need not, as Bell has shown, be so near the rectum but that the proper antiseptic precautions may be taken, putrefaction avoided, and free drainage effected.

### ABNORMALITIES OF THE HEART IN AN EPILEPTIC PATIENT.\*

By GEORGE J. HEARDER, M.D.,  
Medical Superintendent of the Joint Counties Lunatic Asylum, Carmarthen.

E. G., AGED 44, was admitted January 27th, 1873, demented and subject to epilepsy. She had been deserted by her husband on account of her intemperate habits. Her height was fifty-seven inches; her weight one hundred and one pounds. The cardiac impulse was increased in force and area. A loud rough systolic murmur was audible, most distinctly in the line of the sternum, and was prolonged in the course of the great vessels. The radial pulses were very feeble, the left being

\* Read before the South Wales and Monmouthshire Branch.

decidedly the weaker. There was visible arterial pulsation across the neck just above the sternum. The pupils were equal and sensitive. She was certified to be suffering from aortic valvular disease. The epileptic attacks, which averaged five a week, were complicated by syncope symptoms; and she was, therefore, carefully watched, as sudden death was apprehended.

On January 21st, 1878—as on several previous occasions—the medical officers were sent for, as the patient was suffering from a fit of longer than usual duration, and death from syncope appeared imminent. She rallied from this attack; but on the following morning, while standing speaking to a nurse, she fell dead.

The body was examined twenty-four hours after death. The heart weighed twelve ounces. There was a white patch of the size of a shilling on the right ventricle, and another of the same size in front just above the apex. All the cardiac cavities were full of blood. The muscular substance was pale, very soft, and easily torn by digital pressure. Both ventricles were dilated, and the left was also considerably hypertrophied. The aortic valves were competent. The aortic opening was seven-eighths of an inch in diameter; the mitral opening one inch and an eighth; the pulmonary one inch and a quarter; the tricuspid one inch and a half. There were patches of atheroma on the inner surface of the aorta; the free edges of the valve were thickened; and there were calcareous spicula in the attached edges. The aortic valve consisted of only two segments: the anterior being the larger and covering the origin of both coronary arteries; the segments were thickened and somewhat sacculated. The two posterior segments of the pulmonary valve were joined together by their contiguous free edges as far as each corpus Arantii; therefore, the pulmonary valve, as well as the aortic, consisted practically of only two segments. The ductus arteriosus was patent, the opening being one-eighth of an inch in diameter. The innominate and the left carotid arteries arose from the aorta by a common trunk; the carotid crossing the neck at the level of the upper edge of the sternum.

### CASE OF HIGH TEMPERATURE AFTER PARTURITION: TREATED WITH WARBURG'S TINCTURE.

By J. BURNLEY WALKER, M.D., Golcar, Huddersfield.

It has occurred to me that the following brief notes may not only serve as a fitting sequel to the interesting case published by Dr. Playfair, at page 687 of volume ii of last year's JOURNAL, but may also be a guide to the treatment of a class of cases which unhappily are but too common in general practice, and, from the attendant circumstances, probably cause more anxiety to the family practitioner than any other.

Mrs. A. B., aged 42, a spare delicate woman, was confined of her sixth child on January 9th, 1878. The labour was in every respect a natural one, and not attended with more than ordinary difficulty. On the second day after delivery, she complained of a creeping sensation, commencing at the feet and travelling to the face, accompanied by intense throbbing headache, which was followed by burning, flushed face, and extreme thirst. On palpating the abdomen, there was a little tenderness to the left of the uterus. The lochia were offensive, and lactation had ceased. This state of things existed (accompanied with insomnia) for several days; the temperature fluctuated from 101 deg. to 104 deg., with no distinct regularity, except that the afternoon temperature was always the highest. The pulse ranged from 110 to 120. The tongue was dry, fissured, and "leathery".

Without detailing particulars from day to day, I may say that, on January 26th, at 11 A.M., I found her much worse. Temperature 104.8 deg.; pulse 120. The patient was obliged to lie on her back, and could with difficulty speak. The breathing was hurried and shallow. There were continual "creepings" (no distinct rigor). There was no pneumonia. On examination, the uterus was found to be fixed as by adhesions, and on the left side there was considerable tenderness to the touch. I ordered her fifteen grains of salicylate of soda every two hours, and one ounce of brandy every three hours, in addition to milk, eggs, and beef-tea. By the time three doses of the salicylate had been taken, the temperature had fallen to 98.6 deg. and the pulse to 88. The breathing was much slower; there were no creepings; the thirst had gone; the tongue was moist, while there was profuse diaphoresis.

The cure, however, had produced more discomfort than the disease; there was deafness, with distressing noises in the head, which the patient described as intolerable.

On my visit next morning, I found the temperature had risen to

104.8 deg. and the pulse to 132. There was increased tenderness on palpating the abdomen, with some tympanites; the breathing was again hurried and oppressed. The patient's condition was now so critical that I suggested a consultation, and at noon Dr. Clarke of Huddersfield saw the case with me. At his suggestion, I prescribed half an ounce of Warburg's tincture; no food having been taken for an hour previous to its administration. Failing this remedy to reduce the temperature, we determined upon resorting to cold affusion. However, the administration of the tincture was immediately followed by profuse perspiration and refreshing sleep. At 8 P.M., the temperature had sunk to 98.6 deg. and the pulse to 100. The frequency of the respiration had correspondingly diminished. The patient expressed herself very much relieved; she could now lie on her side and sleep for two or more hours at once. I ordered three drachms of the tincture to be given during the night, and one ounce of brandy every hour, as the consequent exhaustion was so marked. Since this, the case has had no untoward symptom. The pulse and temperature remain normal, while the abdominal tenderness has entirely disappeared.

This case needs no comment. The immediate improvement was so marked that, I have no doubt, this patient's life was saved by the timely administration of "Warburg". The case has this additional interest: that cold affusion was not employed, as in Dr. Playfair's; hence more reliance may be placed on the value of the drug, which, since the publication of its formula by Dr. Broadbent, should now no longer rank in the list of quack medicines, but should be added to the armamentarium of every practitioner.

### CLINICAL MEMORANDA.

#### CROUP: DIPHTHERIA.

ON re-reading Dr. Johnson's letter (*Lancet*, February 16th) by the light of his last, in the BRITISH MEDICAL JOURNAL of June 1st, I can readily see how I should have so misapprehended Dr. Johnson's intention; but still, as his views are at present not my views, and as he did not say, but only "meant to say that the membranous exudation which characterises diphtheria, when not the result of direct contagion from a previous sufferer, is caused by a drain-poison", he will the more readily pardon my unintentional misconstruction. Since, however, my misapprehension has elicited from Dr. Johnson so clear and explicit a definition of the point at issue, I regret it the less. And, as the final settlement of this important practical question is the end and object of us all, I hope Dr. Johnson will forgive me, if, notwithstanding his last letter, I still have the hardihood to contend that "a false membrane which has resulted from infection by a drain-poison" may not be diphtheria. It is possible, as stated by Dr. Johnson, "that, in the absence of direct contagion, the occurrence of membranous pharyngitis or laryngitis affords conclusive evidence of infection by sewage-poison conveyed through either air or water"; but I am quite unable to admit that the single pathological symptom "false membrane" always means diphtheria.

ROBERT L. BOWLES, M.D., Folkestone.

#### VARICELLA OCCURRING IN AN INFANT TWENTY-FOUR HOURS AFTER BIRTH.

ON March 17th, 1878, I attended Mrs. M. in her seventh accouchement. On visiting her the next morning, the nurse drew my attention to the child, "who had a rash coming out"; its body was quite clear from any eruption at birth. I found a well-formed vesicle on one wrist, also several red papule on the face and forehead. The following day, another crop of vesicles and papules appeared, and the illness ran the usual course of a case of chicken-pox, lasting about ten days, the infant passing through the ordeal nicely. The mother was free from any vesicular rash, and had had no symptoms of illness whatever; but the other children, six in number, were suffering from chicken-pox in its various stages. Now, I believe the incubation in varicella is from three to four days, with a premonitory fever lasting from twenty-four to seventy-four hours, when the rash appears; how, then, are we to account for a child in so few hours from its birth contracting this disease? Either it must have been peculiarly susceptible to the above contagion, and the usual period of incubation and primary fever was wanting, or else the infection was conveyed through the parent to the fetus *in utero*. I must add that the child had not been taken from, neither had the other children been admitted into, the lying-in room. This case will do away with the theory, held by some of the older physicians, that varicella only occurs in the vaccinated.

HOSPITALS AND ASYLUMS OF GREAT  
BRITAIN AND IRELAND.

## UNIVERSITY COLLEGE HOSPITAL.

IMPASSABLE STRICTURE OF THE URETHRA: WHEELHOUSE'S  
OPERATION: SEVERE URETHRAL FEVER: RECOVERY.

(Under the care of Mr. CHRISTOPHER HEATH.)

FOR report of the following case we are indebted to Mr. A. J. PEPPER, Surgical Registrar.

S. B., aged 31, a man of colour, suffered from gonorrhœa several times. The last attack occurred ten years ago. Two years after this, he noticed that his stream was perceptibly smaller, and at that time he was catheterised, which, he stated, relieved him considerably. Soon, however, the urethral passage began to contract again, and this continued to become worse up to the time of his admission. He had occasional pains in the left renal region and along the groin of the same side.

On admission, the patient was a fairly healthy-looking man, and complained of nothing except a difficulty of micturition, the intervals between the acts varying from one to four hours. The urine, as a rule, came away by dribbles. There was no hæmaturia, and no pain in the lumbar region. Nothing abnormal could be made out on abdominal palpation; pressure above the pubes caused no inconvenience. There was no induration to be felt through the perineum. The passage of a catheter was arrested about half an inch in front of the bulb, and an attempt to reach the bladder was unsuccessful, as not even the smallest instrument could be got through the stricture. There was scarcely any pain either during or after micturition. Temperature normal. The urine was of specific gravity 1022, acid; it contained a trace of albumen, and deposited a sediment of mucus; it contained no sugar.

*Operation.*, December 12th, 1877, three days after admission. The patient was anæsthetised with ether, when Mr. Heath proceeded to perform Mr. Wheelhouse's operation; the patient being placed in the lithotomy position. A beaked staff was passed down to the stricture, and the urethra opened upon it. The staff was then pushed through the wound, and the anterior part of the urethral passage hooked forwards. Each side of the mucous membrane was retracted with forceps, and search made for the aperture into the posterior part of the urethra. This stage of the operation was somewhat prolonged, owing to the difficulty in finding the contracted opening; but eventually a blunt-pointed probe was passed into the bladder, and along this Mr. Wheelhouse's probe-pointed gorget was directed and made to dilate the stricture. A full-sized elastic catheter passed through the meatus, traversed the perineal wound, and slid along the gorget into the bladder. The catheter was tied in.

December 13th. The patient passed a tolerably good night. The urine had been drawn off at intervals by removing the plug from the catheter. To-day, an India-rubber tube was attached to the catheter, and conducted to a vessel containing a disinfectant solution. Temperature 101.3 deg. Fahr.; pulse 123.

December 14th. Yesterday, the urine was mixed with a large amount of blood. This morning, it was of porter colour and fetid, though in quantity good. There was severe pain in the left renal region. Temperature 100.8 deg. Fahr.; pulse 108. The catheter was removed.

December 15th. There was decided improvement in his general condition. The greater part of the urine was passed voluntarily by the wound, but a small quantity escaped from the urethra. Temperature 99.8 deg. Fahr.; pulse 100.

December 16th, 7 A.M. A rigor set in, which lasted for a few minutes. Temperature 104 deg. Fahr. At 5 P.M., a second rigor occurred, and lasted for twelve minutes; the temperature at the time was 104.5 deg. Fahr. Half an hour afterwards, it had risen to 107.2 deg. Fahr. in the axilla. At midday, some blood escaped with the urine. Sulphate of quinine (five grains) was ordered to be taken every six hours.

December 17th. The patient slept well during the night. The temperature this morning was 99 deg. Fahr. The wound looked healthy.

December 19th. The urine was alkaline; it contained no blood, only a trace of albumen, and a copious deposit of mucus. Temperature 100.1 deg. Fahr. He was now taking two grains of quinine every six hours.

December 29th. Since the 19th, the greater part of the urine had escaped from the wound, though occasionally some was passed by the natural passage, and this more when in the sitting than in the recum-

bent position. The wound itself was granulating healthily. The urine was ammoniacal and fetid. He had pain in the suprapubic region, with tenderness on pressure. A No. 12 catheter was passed down to the wound, where some obstruction existed. A No. 6 bulbous catheter introduced from the wound into the bladder. Temperature 99.4 deg. Fahr. He was ordered tincture of hyoscyamus, twenty minims; infusion of buchu, three ounces; to be taken three times a day.

January 1st, 1878. The urine was acid; it contained no sugar; no albumen; there was a deposit of mucus. Temperature 98.8 deg. Fahr.

January 5th. A No. 8 catheter was passed. Some obstruction was met with at the anterior part of the wound.

January 12th. A No. 9 catheter passed easily. More than half the urine was passed by the meatus. There was marked general improvement.

January 26th. A No. 10 catheter passed readily. The wound was nearly healed.

January 30th. The wound was very small. Almost all the urine was passed by the meatus. He had slight cystitis. Temperature normal. His general health was good. A No. 11 catheter was introduced. He was discharged to-day. He could pass a good-sized stream.

REMARKS.—The points of interest about the case are: 1. The nature of the operation; 2. The severe attack of urethral fever; 3. The favourable termination of the case. During the operation, one source of trouble was the hæmorrhage, which, though slight, was sufficient to obscure the view of the parts when the urethra was laid open. The main difficulty, however, consisted in the small size of posterior aperture of the urethra leading from the wound, care being required to avoid passing the probe in the interstices of the tissues and making a false passage. After the probe had been introduced into the bladder, no further difficulty arose. The day after the operation, the urine contained a large admixture of blood, which evidently was not derived from the wound in the perineum, as no external hæmorrhage occurred. The pain in the renal region pointed to reflex congestion of the kidney; and it is interesting to note that it was not until the fifth day that the sharp attack of fever presented itself. The temperature at that time being unusually high, though possibly influenced by some malarial taint, cystitis followed the operation, and it was most severe on the seventeenth day after. Very marked improvement took place on administering buchu and hyoscyamus, so that in two days the urine became acid. Subsequently, no bad symptoms presented themselves, and the patient steadily convalesced.

## SAMARITAN FREE HOSPITAL.

## CONSULTATIONS.

MAY 17TH.—*Abdominal Tumour: Uterine or Ovarian?*—Dr. BANTOCK introduced for consultation a woman, aged 58, suffering from a large abdominal tumour. She had been married twenty-three years, without issue. The catamenia, which had ceased five years ago, had always been regular, lasting four or five days and unaccompanied with pain, excepting for a few hours before their appearance. Her general health had been good. Last summer, she found that her clothes did not fit comfortably round the waist, and at Christmas there was distinct abdominal enlargement, with crampy pains in the left groin, which prevented her from lying on the left side. Both walking and standing caused the patient great discomfort. She consulted Mr. Spencer Wells, who at once recommended her as an in-patient for the hospital. Dr. Bantock observed that the diagnosis of the abdominal tumour, which certainly existed, was a matter of great difficulty. The rapid growth of the new body, the absence of any special derangement during the period of menstrual activity now past, and the conditions detected by vaginal examination, together with the rapid emaciation since the first appearance of the tumour, indicated ovarian disease. On the other hand, there was a very obscure sense of fluctuation elicited by percussing the abdomen—a symptom often observed in cases of soft, elastic uterine fibromata. Dr. Bantock proposed to find out the nature of the tumour by employing an aspirator, before he considered the question of removal. —Dr. GREENHALGH believed that the tumour was a multilocular ovarian cyst, as he found it had commenced soon after the cessation of menstruation, and had increased very rapidly within a twelvemonth. The uterus was not so much drawn up as in ordinary cases of large fibro-myomata of that organ, and the tumour had first been noticed in the left side of the abdomen, without any previous complaint of pressure or discomfort in the pelvis.—Mr. SPENCER WELLS remarked that this was a case where the cervix might be drawn down with a vulsellum forceps, to see whether the uterus were free or not, after Hegar's plan. There was evidently a large tumour, freely movable, which could be readily raised by the hand when applied immediately above the pubes. The growth was sufficiently soft to raise a suspicion of its originat-

ing in the ovary itself; but there was no fluctuation in the tumour, and there were nodular portions to the left, harder than in most ovarian outgrowths; the cervix was hard, and so small that the sound could not be introduced. The tumour was certainly closely connected with the uterus; and, taking into consideration the *facies uterina*, together with the absence of distinct fluctuation, the closure of the os, the hardness of the cervix, and the close connection of the portion of the tumour felt by the vagina with the body of the uterus, there was strong evidence of the tumour being uterine.—Dr. W. H. DAY considered that the absence of fluctuation, the rapid growth, and the close connection of the tumour with the uterus, indicated fibroma of the uterus, or a sarcomatous tumour, but not a cyst of the ovary.—Mr. KNOWSLEY THORNTON stated that the absence of fluctuation, and the general consistence of the tumour on palpation, indicated a soft uterine fibroid; and, from pelvic examination, he was led to believe that it rose from the front and top of the fundus, and was directly continuous with the cervix.—Dr. CHAMBERLAIN could detect no true fluctuation, but there was a wave of fluid, on percussion, over the surface of the tumour, and a feeling of elasticity on palpation of opposite parts of the abdominal growth. The tumour was very hard and nodular, and closely connected with the uterus. The date of its commencement and its rapid growth were against the probability of the whole being fibroid.—Mr. DORAN felt no doubt about the fibroid character of the growth, which, on vaginal examination, could be felt on the left of the cervix uteri. He thought it improbable that it could be continuous with the abdominal tumour, except by secondary adhesions; for that swelling was very much softer, and, though it might be also uterine, it was more probably ovarian. The physical characters and history both indicated sarcoma rather than the ordinary cystic disease of the ovary.—All the staff agreed with Dr. Bantock in recommending exploratory measures before operation.

#### MANCHESTER ROYAL INFIRMARY.

##### FATAL CASE OF OPIUM-POISONING IN WHICH ATROPIA WAS ADMINISTERED.

By F. A. SOUTHAM, M.B., F.R.C.S., House-Physician.

THOMAS H., aged 38, was admitted into the Manchester Royal Infirmary on the evening of April 12th, suffering from symptoms of poisoning by opium. He had been found in bed breathing very heavily about 9.30 A.M. the same morning, and two empty bottles, which had each contained an ounce of laudanum, were lying in the room. Several attempts were made to awake him, but, though unsuccessful, medical aid was not summoned till 4.30 P.M. in the afternoon. A medical man then saw him, and the stomach-pump and galvanism were used; but, all attempts to arouse him failing, he was brought to the hospital.

When admitted, at 7.30 P.M., he was in a state of profound coma; the pupils were contracted to pins' points; the conjunctivæ were insensible. Respirations were about four a minute, very feeble. Pulse very quick and irregular, and so weak as to be with difficulty perceptible. The skin was cold and moist. The complexion was somewhat cyanotic. He was immediately removed to bed, heat was applied to the extremities, and one-thirtieth of a grain of atropia (four minims of liquor atropiæ sulphatis, *B. P.*) at once injected into the arm. Flagellation with the wet towel and galvanism were then applied to the chest.

At 7.45 P.M., one-thirtieth of a grain of atropia was again injected, and artificial respiration was employed alternately with the galvanism and flagellation. Under this treatment, a marked improvement in the symptoms took place; the respirations increased to sixteen a minute, though still very feeble, and attended with loud stertor; the pulse could now be distinctly felt, falling to 84; the conjunctivæ became sensible, and the pupils began to dilate. The patient, however, was still deeply comatose, and unable to be aroused.

At 8.30 P.M., one-thirtieth of a grain of atropia was again injected, as the breathing had become very weak and irregular, being occasionally completely suspended for some seconds. This was immediately followed by another temporary improvement, the respirations again reaching eighteen a minute, though still very feeble. Pulse 84, very weak and irregular. The pupils had now become widely dilated. The condition of profound coma, however, still continued, the breathing again becoming very shallow and imperfect, and from time to time altogether suspended, but being temporarily ameliorated on again employing galvanism and artificial respiration. An attempt to give stimulants by the mouth being unsuccessful, owing to the power of swallowing being abolished, an enema containing an ounce of turpentine was given at 9 P.M., and warm fomentations were applied to the chest, with the view of keeping up the circulation, which had become very feeble. The pupils still remained widely dilated.

At 9.30 P.M., the respirations, which had gradually become feebler

and slower, having almost entirely stopped, one-thirtieth of a grain of atropia was again administered. This, as before, was followed by a marked improvement, the respirations at once rising to fourteen a minute; the improvement was, however, very transitory, as after a few minutes the breathing, becoming very weak and slow, altogether ceased; at the same time, the countenance became more cyanotic, the lower jaw fell, the skin covered with a cold clammy sweat, and the pulse almost imperceptible. Artificial respiration and galvanism were again used and maintained for some time.

At 9.45 P.M., another thirtieth of a grain was injected, but without any effect; and death ensued, from evident failure of the respiratory function, about 10 P.M.

*Post Mortem Examination.*—The surface of the body, especially the back, face, and arms, was mottled and of a dark purple colour; the vessels of the pia mater were much congested, and about two ounces of serous fluid escaped during the removal of the brain. The choroid plexuses were much congested and oedematous; the centrum ovale was more studded than usual with minute blood-points. The stomach was empty and its lining membrane healthy, being covered with a little viscid mucus. Both lungs were much congested.

REMARKS.—The value of atropia as a respiratory stimulant in cases of opium-poisoning is well illustrated by this case; for, under its influence, the respiration at once rose from four to sixteen a minute, and after each subsequent injection a temporary but marked improvement took place. The difficulty appears to be to know how often and in what quantity the atropia should be given; in the present case, the rule as laid down by Wood was followed—viz., of administering a small dose and renewing it as often as there is any tendency for the respiration to show signs of failure: no indication could be drawn from the condition of the pupils, for after the second injection they became very widely dilated, and remained so until the end of the case. Whether a more favourable termination would have followed if the atropia had been given in a larger dose (e.g., one grain), as recommended by Fothergill, it is impossible to say; but, from the length of time which had elapsed before the patient came under treatment (the opium having probably been taken at least eighteen hours before, and in considerable quantity), I do not think it at all likely that the administration of the antidote in larger doses would have been followed by recovery.

#### ADELAIDE HOSPITAL, DUBLIN.

##### CYSTITIS IN A FEMALE SIMULATING STONE IN THE BLADDER.

(Under the care of Mr. BARTON.)

E. R., WIDOW, aged 29, by occupation a nurse, was admitted into the Adelaide Hospital on February 16th, on the suspicion of having a calculus in her bladder. She stated that her health had been failing for several months, and that for the last month she had experienced an uncomfortable sensation in the region of the bladder, with a frequent desire to micturate. The symptoms increased; appetite was lost, and fatigue easily induced. At times, she had shooting pains across the lower part of the abdomen and down the inner part of the thighs. About a fortnight before her admission to hospital, after some exertion, she felt faint, had a severe pain in the hypogastric region, and, after great straining in micturition, passed a considerable quantity of blood, and had to take to bed. The pain, which was excruciating, was unrelieved by passing urine, which she did every half-hour. The urine was acid in reaction, and contained blood and pus. A mass of enlarged glands was noticed on the left side of the neck. Mr. Barton sounded the bladder for stone, but failed to discover one. Bland injections were made into the bladder, and tonics and anodynes administered, but without effect. Mr. Barton, therefore, determined to dilate the urethra, which he did by means of Weiss's dilator, by two operations, with an interval of fourteen days; after which, the urethra was so expanded as to admit the index-finger freely into the bladder. The mucous membrane of this was quite rugous; there was but slight hæmorrhage, and the urine trickled away for about twelve hours. She steadily improved after this, and left the hospital on April 6th, with complete control over the bladder; all pain was gone and her appetite was good; the urine was healthy, and the glands in the neck much reduced in size. Upon each occasion that the dilator was used, the patient was placed under the influence of chloroform. The dilatation occupied nearly a quarter of an hour. It was carried as far on the first occasion as to admit the tip of the index-finger into the urethra, but not into the bladder. This was followed by such marked relief that it was hoped no more would be required; but the symptoms persisting, although in a mitigated degree, the second dilatation was performed, when the index-finger was freely passed into the bladder; incontinence lasted only one day. Complete cure followed.

## REVIEWS AND NOTICES.

THE ANTIDOTAL TREATMENT OF DISEASE. By JOHN PARKIN, M.D.  
Part I. London: Hardwicke and Bogue. 1878.

THE author begins his work by inserting a number of quotations from various sources to prove that the art of healing is at present in a very "lamentable state". This he traces to two reasons, the first of which "has been the adoption of so many new theories, and the laying aside of that simple and scientific mode of treatment pointed out by the father of medicine himself"; and the second is "that we have remained up to the present time in complete ignorance of the immediate and proximate cause of the majority of diseases". That we may no longer remain in this state of primeval darkness, he proceeds to enlighten us on the last point; and, after a long and rambling argument, he informs us that the cause of all febrile and all inflammatory conditions of every description is the same; viz., malarial poison. Taking ague as the type of malarial disease, he informs us that "in the cold stage of the disease, the poison is situated in the capillaries of the lungs. . . . In the febrile stage, the same matter is confined in the systemic capillaries, having been transported there with the current of the blood on the termination of the cold fit"; whilst during the intermission "it is contained in the venous system, into which it has been propelled on the termination of the febrile stage". Having thus proved to his own satisfaction that the ultimate pathology of a large number of very diverse morbid conditions can be brought down to the one focus of malarial poison, he disposes with equal ease of the question of their rational treatment. "There are only two methods of treatment that can be scientifically adopted; one is to neutralise the offending matter by the administration of an antidote, or, failing this, to cause its expulsion."

Without altogether ignoring the latter method, it is the former which has attracted the author's particular attention; and it is here that he has made his great discovery. Believing that his universal malarial poison is closely allied to the "class of poisons termed septic", he was led to infer that "carbon and its compounds would be or ought to be antidotes for the poison . . . and specifics for the diseases arising from the operation of malaria in the human frame". Considering carbonic acid to be the simplest form in which to administer carbon, he treats all descriptions of disease which come within his wide-embracing category with the ordinary Mista effervescens of our hospital pharmacopœias. This is all:

"Parturiunt montes, nascetur ridiculus mus."

Two good-sized volumes are necessary to prove inductively and deductively that effervescing mixture may be given to feverish patients. Except that the use of quinine is decried in ague, the result arrived at is harmless enough; but the author would have consulted his reputation for logical argument better had he followed Lord Mansfield's well known dictum, and stated his results without attempting to give the reasoning by which he arrived at them.

PUBLIC HYGIENE IN AMERICA. By HENRY I. BOWDITCH, M.D.  
London: Trübner and Co. 1877.

THE volume before us contains a centennial discourse delivered before the International Congress which was held at Philadelphia in 1876, but the discourse has been greatly expanded, and with appendices, in which are embodied the data that formed the groundwork of the address, it now occupies a thick volume of nearly five hundred pages. The address, as it at present stands, consists of two parts, in the first of which the author gives an account of the birth of the science of preventive medicine, and of its gradual development up to its present state. In the second part, a summary is given of the answers returned by a large number of medical men in all parts of the Union to a series of questions formulated by Dr. BOWDITCH, with the view of ascertaining what amount of attention was being paid to the subject by the legislatures of the different States. Both divisions of the subjects are full of interest, and the latter will very probably be of great service in America, by calling attention to deficiencies in the hygienic condition of the towns, and by pointing out the directions in which reform is needed.

In the first division of his subject, the author divides the history of sanitary science into three epochs, the first comprising the period ending with the year 1832. This he terms the epoch of "systems" of medicine, when everything was believed of drugs and nothing was expected from nature in the curing of disease. But then came the reaction first started by the teaching of Louis, when medical scepticism began to show itself, and it soon led to an almost total disregard for drugs, and an overweening confidence in the power of nature to right

herself. The pendulum having thus swung to its full extent in the opposite direction, it took its fresh start in America, in the opinion of the author, in the year 1869, when the first State Board of Health was legally organised. Dr. Bowditch is very sanguine that we have entered upon the final epoch of medical development, and that we shall advance steadily into the far future on our road of improvement. We must confess to being less hopeful of having reached the broad straight road to perfection, and we fear that action and reaction will govern our movements as heretofore. At the same time, we think the author is fully justified in attaching great importance to the period when the study of preventive medicine was first seriously begun; and it cannot be doubted that it is from this side that disease will be most effectually attacked in the future. This, moreover, is a battle in which, as Dr. Bowditch points out, the whole community, lay as well as medical, can, and indeed must, take part; and the questions, the answers to which form the second part of his discourse, were drawn up with the principal view of ascertaining to what extent the lay authorities were alive to this fact, and were accepting the responsibilities devolving upon them. We cannot say the answers were encouraging, for in a large majority of states, it appeared that the legislatures were not at all alive to their duties; were unwilling to spend any money to improve the health of their people; had passed no laws for that purpose; whilst the drainage, even in such cities as Boston, appears to be still in a very primitive condition. Public opinion, however, seems to be waking up on the subject; and we think the present volume is eminently calculated to give impetus to the sanitary movement which has now been started. We wish Dr. Bowditch every success in his righteous endeavours; and we trust that when the next sanitary census is taken, the returns will show a much more satisfactory state of things than at present exists.

A NEW SYSTEM OF MEDICINE ENTITLED RECOGNISANT MEDICINE, OR THE STATE OF THE SICK. By BHOLANATH BOSE, M.D., Her Majesty's Indian Medical Service. Pp. 204. London: J. and A. Churchill. 1877.

PRINCIPLES OF RATIONAL THERAPEUTICS. By the same Author. Pp. 88. London: J. and A. Churchill. 1877.

THESE essays are an extraordinary compound of old ideas under new names—tirades against prevalent teaching, and absurd self-assertion, with a certain amount of ingenious speculation, quaint phrasing, and fantastic comparison. We do not often review an Indian treatise, and regret that we have not better words for this one; but a few extracts will speak for themselves. "All diseases may be said to have a two-fold action on the living frame—viz., a forward and a backward *at the same time* (?): the forward is more or less circumscribed and most prominent, and is, in fact, the disease, including symptoms; and the backward, which is equally manifest, but pervades the whole system, is what constitutes the *state* of the patient." (Page 4.) "All our acquired knowledge is and can be but of three kinds—viz., of effects, of causes, and of states. . . . A state or states, call it property, attributes, relations, etc., must be the only condition for a thing to be, or the existence or being of a thing; it is the only possession of an existence—God, man, and the universe: it is the great symbol of life: and lastly, it is alone, so to speak, the chief clothing, the ornament, the dress, the beauty, the expression, and the tangibility or cognisability of all beings." (Page 11.) [We really think our author has made a special study of Bardsolph's speeches.] "Where are we then to look for the state between the symptoms and the disease? Shall we find it in semeiology, etiology, diagnosis, etc.? Does the student proceed from symptoms to the state of the body, and then to the disease? . . . Not so: the first thing he does is to learn the name of the disease; symptoms follow; then diagnosis, prognosis, etc. To him the condition of the sick is a secondary event scarcely worth consideration. . . . He is referred to a mass of undigested, absurd, and contradictory opinions, or to vague expressions, as debility, etc. It appears as if he were blindfolded during this voyage through the state of the body, lest some terrific scene should affect his too tender eyes, and frighten his innocent mind. His theories—like those of his teachers, being chiefly founded on symptoms, the least important part of a pathological whole, and often on some idols of imagination—are like so many gunpowder plots, which terminate sooner or later in an equal number of explosions, each blowing off thousands of our race, who unfortunately happen to be under their mortal influence. The purpose of our present inquiry is not to delineate disease and point out symptoms, but to unfold and develop, as far as lies in our power, the intermediate condition of the sick, or the principle of morbid causation, by which our health is chiefly undermined and death works its way."

With regard to the author's meaning of "*recognisant*", he explains

that every component part of the body is endowed with a certain sense peculiar to itself, by which it knows and performs its function. "Thus the muscular fibre takes cognisance of its stimuli, and contracts; in other words, the muscle is irritable; that is to say, it has a sense of its own, by the exercise of which contraction takes place." [Bardolph again.]... "These senses are born with the parts in which they reside... and are connected by means of nerves to fulfil specific ends, as the individuals in a republic. Their peripheral extremities take cognisance of events, of which their central terminations (brain-cord-ganglia) take cognisance, occasioning a sensation." Are not these all but synonymous with the well-known terms, *direct* and *reflex*? Thus, Dr. BOSE instances muscular contraction under galvanism—"in which neither the muscular nerve, the brain, cord, nor ganglia take part"—as a spasm resulting from a direct impression on the muscular tissue, that is, a *cognisant* spasm, which would be *recognisant* if excited by motor nerves. "A cognisant action or cognisance is the result of an independent exercise of the inherent power or sense with which each organ is provided. On the other hand, a recognisant action is always a dependent phenomenon. Every disease is a cognisance struggling with nature, *i.e.*, recognisance. In hepatitis, the distension of the organ, the effusion of serum, pus, and lymph are *cognisant* phenomena, and pain, fever, vomiting, etc., are *recognisant*. The modern physician is too much occupied with *cognisant* functions; indeed, his knowledge of *recognisance* is extremely limited, and does not extend beyond such expressions as fever, inflammation, tonicity, etc."

In the chapter on Motion, we are informed that motion of some kind seems essential to organisation; that no matter can be said to be truly fixed. "The loftiest mountains, the great and magnificent cities, the silent and solemn pyramids, and the calmest ocean, are all moving through the infinity of time and space... Every existence has a certain age... age, in fact, is almost synonymous with motion" (!). [The number three is of much importance in the New System of Medicine.]... "There are three primitive motions—the ciliary, the tubular, and the cellular. ... There are also three varieties of spasm: (1) The complete existent spasm, wherein circulation is excited (hysteria-cholera); (2) The partially coexistent spasm; and (3) The complete coexistent spasm. Rheumatism is of spasmodic nature."

Concerning the "continuity of animal functions", we are informed that there are three digestions: the first is simply "alimentation"; the second realimentation (comprising suction of chyle and lymph, their mixture with venous blood, etc.); and "nervous digestion" or super-realimentation, whereby the nerves are nourished. But the grandest of all digestions, the final stage of alimentation, is spiritual digestion (!) ... The knowledge of God so derived is the last form of *chyle*, the divine food, which we offer our Almighty Father to receive his eternal benediction and peace!"

A sensation is called "sentient accordance", and a motor influence is "motor accordance". "The body in a state of concordance may be compared to a wedge jammed in between two powerfully compressing surfaces—viz., the external world, and the brain, spinal marrow and ganglia, each, as it were, striving to meet the other in close approximation by their peculiar impressions through the intervening wedge". And again, "The mind, with the ordinary senses and the brain, serves, so to speak, as a guardian to the flesh against its external dangers, and watches over the exportation from, and importation to, the corporeal country—the body. It is, as it were, the military department of the animal, with a good commissary-general at its head."

In treating of the "humours in disease", we are gravely informed "that it is not improbable that in many cases an abnormal state of the epithelial membrane is an immediate cause of disorder to the secretive functions. Many of the skin-diseases attended with scaling, which sometimes baffle the best conducted treatment, are, in reality, instances of epithelial disorder".

"... When we have fulfilled our task, we shall ask our professional brethren if they are prepared to cast into eternal oblivion another great bugbear in medicine, and an illusion still more frightful than inflammation, viz., fever—a term which has no meaning in science, and, to say the least, has been a labyrinth of confusion in all ages. Fever is really determination and congestion of the whole frame, and is better called *kyātis* (from Sanscrit *kyā*, the body); and there may be current *kyātis*, recurrent and concurrent ditto." (Page 157.) Are we much wiser than before?

As an instance of the application of the nomenclature of Dr. Bose, we recommend to the Committee on Hydrophobia the following definition. "It = general existent (convulsions) and partial coexistent (lockjaw) and concordant spasm (tonic spasm) of voluntary muscles and excessive spinal motor accordance and perverted mental accordance (fear of water) and canine poisoning."

The second and smaller essay commences with the description of an imaginary patient, Gullible Plastic, giving his interviews with his housemaid, his mother, Mr. Quack, Mr. Aubant (*aub*, water), Mr. Dilution Globule, and Mr. Biggy Ball, and other M.D.s (or mad dogs), in a strain rather beneath that of an average Punch. But the real object of the *brochure* is "to elucidate vital drug-power in its entirety, to reconcile professional differences of opinion, and to raise therapeutics on a basis of common sense to something like a precise art". [This in seventy small pages.]

From a "broad and philosophical study of the present chemical constitution of our globe", our author concludes that "it behoves us, as the oxygen element, to first reduce the housemaids, quacks, *et hoc genus omnes* (*sic*), into speechless stones and ashes! then to combine with the hydropath (the homo-hydrogen) and homœopath (the homo-nitrogen) or compel them to combine into therapeutical water and air, in order that we may, as it were, by a rational convulsion, be nature's true handmaids, and hope to be the real saviours of life, when the vital spring is muddy, or Death prematurely knocks at the door".

After a few lines devoted to quinine, which is, as we are informed, an irritant to gastric mucous membranes, a narcotic, sedative, and tonic, we have a disquisition upon "tone" and the varieties of *organic* life. Of this there are two principal ones: 1. The simple cell, cilia, or fibre-life; and 2. The tubulo-cell life, which may be uni-tubulo-cell, or bi-tubulo-cell, or tri-tubulo-cell, or per-tubulo-cell or intellectual life. If we have any doubt about this, we are advised to study nature well and see. It follows that there are cell-medicines and tubulo-etc.-medicines. What our author would, we suppose, call the *principles* of his therapeutics are, such as that cell-medicines must be bland and inoffensive—not too discordant—must be minutely divided and absorbable, must supply elements of blood, and act continuously; but we can find no extraordinary improvement on the usual teaching in these statements, nor in the division of cell-medicines into cell-tonics, cell-laxatives, and cell-alteratives, nor in the idea that these act through the medium of the liquor sanguinis. Neither is it specially new or definite to presume that, while "iodine and mercury operate equally on all parts, iron, strychnine, and arsenic prefer to act respectively on the blood-corpuses, sarcoous particles, and cutaneous cells, and that quinine, nitre, and digitalis tend to preponderate their forces on the nervous, renal, and circulatory systems". Arsenic acts, we are informed, by a "preferential operation on dermoid structures" either "by destroying acrogenous vegetation, or by indirect alteration of the derma, or by counterirritation, obviating irregular nervous accordance, and the spasm in which recurrent *kyātis* originates" (!). There is a quaint truth in the including of the following amongst per-tubulo-cell or mental medicines. "The direct supporters of cerebral tone may be enumerated as contentment, cheerfulness, liberty, personal and social independence, wisdom, hope, confidence, etc. Its relaxants will be discontent, wretchedness, dependence, stupidity; and, lastly, its alteratives would be good-breeding, patriotism, intellectual and moral culture, religion, etc."

## SELECTIONS FROM JOURNALS.

### SURGERY.

AIR IN VEINS.—II. Fischer (Volkmann's *Sammlung Klinischer Vorträge*, No. 113) discusses the questions arising concerning embolism from the admission of air, and describes the following experiments which he has carried out. 1. From a broad cut through the internal jugular vein at the lower part of the neck, there follows death; and from such a cut in the axillary vein at the level of the thorax, there follows generally in a few minutes the death of the animal, after plainly audible entrance of air, the symptoms being those of asphyxia. On *post mortem* section, immediately performed, the right heart is found dilated, filled with air and frothy blood; and so also the pulmonary artery down to its smallest branches. 2. If a firm pierced cylinder be introduced into the larger veins of the body, death occurs after from five to fifteen minutes, with gradually increasing restlessness and constantly growing asphyxia. This applies to the external jugular vein, the veins of the arms, and large veins of the thigh. 3. If a large quantity of air be rapidly forced into the veins of guinea-pigs, death of the animal will be caused, with the appearance of suffocation, whatever veins be operated on, even the smallest in the body. When, however, air is slowly and steadily introduced, death of the animal results equally; and it only survives when a very small quantity is introduced—as an example, from ten to twenty *centimètres* in half an hour. Thus the entrance of air into the veins is highly dangerous under all circumstances; and it appears that even the slow entry of smaller quantities is more mis-

chievous than might have been supposed from the researches of Uterhart, Laborde, Pirogoff, etc.

**THE TREATMENT OF HÆMORRHOIDS BY FORCIBLE DILATATION.**—Dr. W. Wannehroucq (*Bulletin Médical du Nord*) considers the treatment of internal hæmorrhoids by forcible dilatation of the sphincter ani as a most valuable surgical process. In most cases, medical means suffice; where surgical aid is necessary, however, the abrupt distension of the sphincter by the fingers gives immediate relief, and commonly effects a permanent cure, dispensing with either Salmon's operation (the best of all surgical proceedings for ablation) or cauterisation, whether by the actual cautery or by saturated solution of chloride of zinc.

**INTERMITTENT HYDARTHROSIS OF KNEE-JOINT.**—M. Panas and M. Verneuil have reported to the Société de Chirurgie two cases of intermittent effusion into the knee-joint. M. Panas' case had a perfectly regular intermittent character. It was in a young woman aged 22, who had never suffered from any joint-inflammation, and had no apparent diathesis. The effusion recurred at intervals of fifteen days, and lasted a week. These intermittent attacks in each case commenced soon after accouchement. They lasted for some time, and were apparently uninfluenced by quinine or iodide of potassium.—*THE BRITISH MEDICAL JOURNAL* of February 3rd, 1872 (page 128, column 2) contains a notice of two cases of intermittent effusion into the knee-joint, in the practice of Dr. Löwenthal of Berlin and Dr. Bruns of Tübingen. Both patients were females. In Dr. Löwenthal's case, the attacks were suspended during pregnancy; in that of Dr. Bruns, relief was obtained by the administration of arsenic with quinine, after quinine had failed.

#### ANATOMY.

**RELATIVE CALIBRE OF THE TRACHEA AND BRONCHI.**—From his researches on the relative calibre of the trachea and bronchi, M. Marc Sée draws the following conclusions. In the normal state, the united calibres of the two bronchi are equal to the calibre of the trachea. It may be added, as the result of the measurement of a limited number of cases, that the united calibres of the bronchial divisions are equal to the calibre of the bronchus from which they spring. The respiratory tubes, therefore, are a cylinder, and not a cone. In pathological states, the equilibrium between the capacity of the trachea and that of the bronchi may be destroyed either in favour of the bronchi, as in chronic tuberculation, or of the trachea, as in emphysema.

#### OBSTETRICS.

**USE OF THE FORCEPS IN PARTIAL DILATATION OF THE OS UTERI.**—Dr. A. M. Fauntleroy, (*American Journal of Obstetrics*, Jan. 1878) advocates the use of the obstetric forceps before the os uteri is dilated, in the following cases: 1. When the head descends immediately without the intervention of the liquor amnii; 2. In placenta prævia (Dr. J. S. Eshlemon of Philadelphia is said to have been the first to apply the forceps in placenta prævia through an os uteri of only one and a half inches in diameter). He would also resort to the forceps in the following cases: 1. When the foetal head, from malposition or inertia of the uterus, may become fixed; 2. When labour is retarded by either absolute or relative disproportion of the foetal head to the pelvis; 3. In all cases of *ante partum* convulsions, where there is sufficient dilatation; 4. In occipito-posterior positions, where traction alone, or traction and compression, will assist rotation to the front; 5. In some face-presentations, and in some cases of pendulous uterus; 6. When the vagina is so rigid as to seriously obstruct labour; 7. In breech- and foot-presentations, where the foetal head is not readily delivered, the forceps may be used as recommended and practised by the late Dr. C. D. Meigs of Philadelphia. Dr. Fauntleroy's method of application is that called the pelvic, *i.e.*, application of the blades of the forceps along the sides of the pelvis, and making traction according to the "curve of Carus".

#### MEDICINE.

**SUDDEN DEATH IN DIABETES.**—Dr. Jules Cyr, in a very interesting memoir published in the recent numbers of the *Archives Générales de Médecine*, has given an account of several cases observed at Vichy, in which death has occurred suddenly, from which he concludes that in some cases, and those the most numerous, the persons have been surprised in a state of health which gave no reason to suppose that so sudden and disastrous a result would occur; others have been attacked by acute diabetes; others have arrived at an advanced period of emaciation due to diabetes, so that the fatal termination was not

surprising. In all these cases, three principal stages or symptoms were observed with considerable constancy: 1, excitement; 2, dyspnoea; 3, coma. The period of excitement is manifested by some incoherence, vivacity, and rapidity of speech with some indistinctness, vague *malaise*, and disquietude going on even to anguish. To this excitement succeeds difficulty of breathing, occurring suddenly and sometimes voluntarily; large expirations made with effort; the thorax-muscles acting vigorously, the lungs dilating, and nevertheless oppression persisting, so that the air which penetrates the lungs appears not to be acting on the lungs, and the gaseous exchange to be impeded. The blood has, as it were, lost the faculty of revivifying itself in contact with the atmospheric oxygen. This stage is the most characteristic. It is followed by exhaustion and coma; and death occurs sometimes in twenty-four hours, sometimes in less. *Post mortem* examination was made in eight cases out of thirty which were observed. The most variable lesions were recognised: congestion of the abdominal viscera and of the lungs, fatty degeneration of the pancreas, œdema of the lungs and of the glottis, congestion of the pia mater, etc.; and sometimes nothing at all. The diagnosis is difficult, if the existence of diabetes be not previously known. The pallor, the total absence of contractions or convulsions, the complete collapse, and the sometimes spirituous odour of the breath, characterise this coma; and of course the examination of the urine reveals its true origin. No treatment has appeared to produce any good result. The cases are especially those of young subjects between twenty and thirty years, which coincides with the well-known clinical fact that diabetes is the more grave in proportion as the subject is the less advanced in age. The determining cause of the symptoms has appeared to be excessive fatigue, long journeys, etc. Among the diverse theories which have arisen to explain these facts, two appear specially acceptable. The first—that of acetonaemia and the poisoning by acetone produced by the abnormal formation of glyucose or paraglyucose—is referred to. Acetone is a stupefying substance, which by its action at once resembles ether and alcohol. It appears, therefore, very natural that the cause of sudden death in the course of diabetes may be attributed to poisoning by this substance. The second theory—hyperglycæmia—explains also the succession of phenomena. The retention of sugar is a consequence of the diminution of the urine and sugar excreted, whence a change in the composition of the blood; sudden arrest of the vital phenomena, and cessation of the oxygenation of the blood, whence dyspnoea, muscular resolution, and coma. This anoxæmia would produce a rapid death, and without applying specially to cases ending in three to four hours. These theories, however, are not universally applicable, and further researches are required. These researches are especially interesting in connection with the clinical study of acetonaemia in our pages.

#### OPHTHALMOLOGY.

**ESERINE AND PILOCARPINE IN EYE-DISEASE.**—Dr. H. W. Williams, in the *Boston Medical Journal*, March 14th, 1878, presents a summary of the value of the above remedies in eye-diseases. Experiments by numerous investigators have shown that eserine has the following action. The activity of the circulation is increased, the pressure within the anterior chamber is lessened, the action of accommodation is excited, and the radius of curvature is lessened. The indications for use follow directly from the mode of action. Thus in all corneal ulcers, in suppuration after cataract operations, in glaucoma, its value is unquestioned. Its clinical effects are these. A drop of a solution of sulphate of eserine (two grains to the ounce) causes the pupil to contract strongly in about fifteen minutes, and this effect continues for eight hours. The application causes little or no pain. A solution of eight or ten grains of borax to an ounce of water may also be used twice a day, or oftener, to lubricate the ulcerated surface and soothe its irritability. In phlyctenular or herpetic eruptions of the conjunctiva or of the epithelial layer of the cornea, eserine is of service especially when photophobia is present, and is far preferable to atropia. In traumatic or gonorrhœal ulceration, in ulcerations of the cornea in persons advanced in life or following exhaustive disease, and in creeping ulcer (*ulcus serpens*), eserine has been useful. The circum-orbital or supra-orbital pain, often accompanying these ulcers, has been relieved in a marked degree as soon as the remedy had time to act, and the ulceration has assumed a healthier aspect. In paralysis of accommodation and mydriasis resulting from diphtheria, measles, or scarlatina, eserine abbreviates the abnormal condition. In paralysis of the ciliary branch of the third pair resulting from exposure to cold, it is equally useful. In hysterical photophobia, eserine forms an important part of treatment. The chlorhydrate of pilocarpine differs in its effects in that it produces less conjunctival irritation, less supra-orbital pain, and less spasm of the accommodative power.

## REPORTS AND ANALYSES

AND

### DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### NEW TUPELO TENT FOR DILATING THE OS AND CERVIX UTERI.

THE material of which these tents are composed is the root of the tupelo tree, which grows in swamps and wet places in Georgia and Florida. It consists of finely grained but soft woody tissue, the fibres not being straight, but interwoven and collected in bundles. The tents are cut of the required length and from four to ten times thicker than they

are intended to be for introduction, and are reduced to this size by hydraulic pressure; they are sometimes made hollow, with an internal metallic tube to allow the escape of fluid during the menstrual period, as advocated by Dr. Sassdorff in the *New York Medical Record*. The following are the advantages said to be possessed by these tents over those made either of sponge or sea-tangle. 1. Being smoother and firmer, they are much more easily introduced; 2. Being very light and absorbent, they quickly receive sufficient moisture to expand them and keep them *in situ*; 3. They are probably themselves of antiseptic nature, or at least will not decompose the fluids with which they come into contact; 4. They have none of the offensiveness always accompanying sponge or sea-tangle tents, and are not likely to induce septic poisoning or local irritation; 5. The rapidity with which they expand when in contact with the secretions of the uterus is one of their chief advantages, the time required for complete expansion varying from one hour in the smallest to six hours in the largest; 6. The firm and even pressure they exert is calculated to effect a beneficial alterative influence on the tissues upon which they operate; 7. The difficulties encountered in removing sponge and sea-tangle tents are obviated in this material; they will not break or fracture when dry; nor when moist, will they peel off and leave small particles adherent to the mucous membrane as sometimes happens with other tents; 8. Their dilatable properties may be roundly stated to be from the size of a goose-quill to that of a sixpence. They are conveniently packed in neat boxes, each containing one dozen assorted sizes, and are moderate in cost.

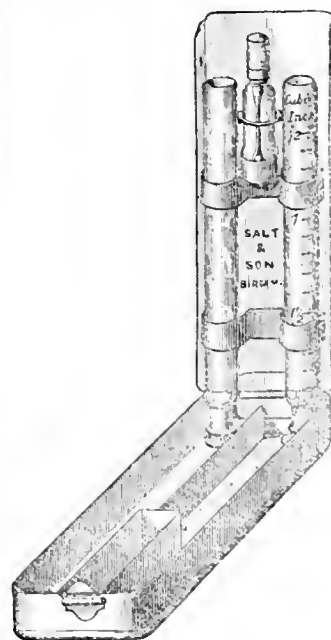

#### AN IMPROVED FORCEPS FOR DEPILATION.

MESSRS. ARNOLD AND SONS of Smithfield have forwarded to us an improved forceps for depilation, of which the accompanying woodcut is an exact copy. In length, this instrument measures five inches and a half. It is intended to be taken in the hand and held horizontally, or at a right angle, to the head of the patient. There is thus secured a great increase of power in manipulating the affected hairs, and the process of depilation can be carried on without the inevitable fatigue

to the finger and thumb resulting from the use of the ordinary depilating forceps. The end is somewhat curved, or rather bent at a slight angle, and thus one or many hairs, as required, may be readily seized. It was made at the suggestion of Dr. Dyce Duckworth, who warmly recommends it as being efficient and convenient in use, and as being likely to render much more popular the practice of depilation, which he believes has, by reason of the unsuitableness of the instruments hitherto usually employed for the purpose, often been neglected or very imperfectly performed.

#### NEW CASE FOR TESTING THE PRESENCE OF SUGAR IN THE URINE.

IN the BRITISH MEDICAL JOURNAL of March 2nd, was a note descriptive of a little apparatus I had devised for the detection of sugar in urine by fermentation. The plan proposed was an extemporaneous adoption of common, inexpensive, and constantly at hand materials, giving a perfectly reliable result. Since then, Messrs. Salt

Fermentation Test for Urine.

of Birmingham have most successfully carried out my ideas of a more complete and permanent arrangement in every respect desirable, combining portability, facility of use, and certainty of result. An inspection of the wood-cut will show this.

The bottles are supplied with glass stoppers, perforated by a capillary opening, and having a cross-shaped notch on their outer surface, allowing the escape of fluid when inverted, if gas be eliminated from its contents. One of the bottles is graduated into tenths of a cubic inch for an approximate quantitative estimate; the other bottle is plain, not graduated: they are most conveniently retained in their proper position by metallic clips, affording security under use, and safety of packing when the case is closed.

Messrs. Salt have added a capped and stoppered bottle for the yeast, having a spoon reaching to its bottom, and holding about the quantity of ferment required. The whole apparatus is well got up, and will, I doubt not, prove valuable, easy of use,

and perfectly effective. The wood-cut is a fair representation of the case, and is drawn to a scale of one-fourth of actual size.

In using, the graduated bottle is filled to the very brim with the suspected urine, a little yeast is to be added, the stopper is then to be firmly placed in the neck of the bottle, the superfluous urine escaping through the opening, leaving the bottle perfectly full, without a particle of air being retained. It is then inverted, and placed, with its stopper immersed in a thin stratum of the urine, and exposed to a gentle temperature. If sugar be present, fermentation soon begins; gas is eliminated, collecting in the upper part of the bottle, and driving out portion of the urine through the opening in the stopper. The second and ungraduated bottle is filled with the same urine, and treated in the same way as the first, but no yeast is to be added to this; when placed beside the other, it affords a sure means of comparison; this bottle (from the absence of ferment) remaining quite full, no gas being given off, the sugar remaining undecomposed.

TITOS. BIRT.

IMPROVED FORCEPS FOR DEPILATION.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st.

Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 8TH, 1878.

### THE METROPOLITAN COUNTIES BRANCH AND ASSOCIATION VOTING.

THE Metropolitan Counties Branch has been displaying a good deal of activity. It has completed the arrangements for establishing a district organisation, which will provide local centres of scientific and social meeting for the one thousand two hundred members of the Association included within its district. The evening meetings to discuss the present position of the provident medical dispensary system, under the guidance of Mr. Holmes, have given a further distinct impetus to a question which this Branch has for many years not ceased to press upon the attention of the medical profession and the public, and they have greatly helped to provide a solution. The co-operation of the Charity Organisation Society, and notably of Sir C. Trevelyan and Sir Rutherford Alcock in that Society, is producing a great practical effect in London. We hear that three metropolitan free dispensaries have during the last few weeks resolved to transform their system and to adopt provident restrictions. The papers of Dr. Seaton and Dr. Green on vaccination, read at a meeting on May 22nd, constitute a new departure for a discussion of a question which is sure sooner or later to engage national attention.

But on Wednesday, May 15th, an afternoon meeting was held to consider the Bills for the amendment of the Medical Act now before Parliament. The experiment of an afternoon meeting was, however, a very unsuccessful one as far as numbers went. Instead of the full audiences which attended Mr. Holmes's paper, and the animated discussion which was carried on through two sittings, there were not more than twenty members present at any time, and the meeting was, we should imagine, the smallest meeting of the Branch ever held. The importance of the speeches made by persons who have officially given so much time and attention to the question of Medical Reform as Dr. Waters, Dr. Quain, Professor Haughton, Dr. A. P. Stewart, and Mr. Nelson Hardy, deserved a much larger audience. A very full report of these speeches, which give a lively picture of the views of the two different parties on this subject, has been published in the JOURNAL; and, like the judge who consoled himself for the narrowness of his court by the consideration that "he sat in the newspapers", this report has, it is hoped, served in some measure to console Dr. Waters and Dr. Haughton, as well as their opponents, for the small numbers who assembled to hear the most exhaustive *vis à vis* debate on the subject of medical reform which has taken place in the Association since 1870. The resolutions, it was stated, had been circulated in print to every member of the Branch prior to the meeting, and the smallness of the attendance served once more to show how great is the political apathy of members on this question, and how much easier it is to get their signatures to a document presented to them than to induce them to take the trouble to attend personally to argue the subject or to support their champions by a personal vote on either side. One resolution, as circulated, declared distinctly "that it is not expedient to oppose the progress of any Bill which may contain satisfactory provisions for the establishment of conjoint examining boards, the amendment of the penal section of the Medical Act, and the registration, under proper supervision, of foreign and colonial

degrees and diplomas, on account of its not including provision for the direct representation of the profession in the Medical Council"; in other words, that it is not expedient to repeat the policy pursued by the Reform Committee in 1870 in rejecting Lord Ripon's measure of medical reform, but that, if the Duke of Richmond's Bill should, when amended, give conjoint boards, a satisfactory penal clause, and satisfactory regulation of foreign and colonial degrees, it would not be desirable to reject it on the sole ground that it does not give "direct representation". This resolution runs counter to the voting-papers issued by the Medical Reform Committee, which have been largely signed in the metropolis as well as elsewhere. Nevertheless, not twenty members attended to express or to hear any opinions; and, of those who did, the majority voted in the sense of the resolution. Many hundred written votes have, we believe, been sent from the metropolis against the sense of this resolution, but its circulation did not induce as many as twenty to attend.

The same apathy was noted in the case of the special general meeting of the whole Association held at Birmingham lately. Although "burning questions" were to be discussed, including those of the "privileges of lady-members" of the Association, which had been the subject of much apparent preliminary excitement, and although Dr. Grigg stated that he had received two thousand written adhesions to resolutions which he moved, also after somewhat vivacious preliminary incidents,—out of the seven thousand members of the Association, not more than two or three score members outside the limits of the Birmingham and Midland Counties Branch attended the meeting; and, whereas the vote which Dr. Grigg had taken is alleged by him to have furnished two thousand in favour to forty against his resolutions, the meeting was practically unanimous against him. Results such as these might, on critical occasions, seriously embarrass administrative action; and, out of many morals which might be deduced, one is prominently deducible, and will probably command general acceptance; and that is, that it would be well either to be more chary in signing voting papers, or to be more active and consistent in attending to take part in debates and *vis à vis* votes subsequently on the same subject. The voting-papers in the first case were unauthorised, and only the vote of the meeting has official weight; but in the case of the meeting of the Metropolitan Counties Branch there is a direct official contradiction. The votes of the metropolitan members on papers are, we believe, distinctly in favour of the rejection of the Duke of Richmond's Bill, even if granting all the other cardinal points of medical reform, if it did not give direct representation. The vote of the Metropolitan Counties Branch—after officially circulating to every member of the Branch the resolution we have quoted—is in favour of passing the Bill under these circumstances; and this resolution will have been forwarded to the Duke of Richmond, who will thus have received very contradictory results from the same section of the Association, and can hardly fail to draw unsatisfactory conclusions as to the earnestness of members or the care with which their opinions have been formed on the subject.

### UNIVERSITY INFLUENCE ON METROPOLITAN MEDICAL TEACHING.

#### II.

THE benefit to our students from the mutual association proposed by the resolutions adopted by the Convocation of the University of London in something beside athletics would be great. Except in three or four of the largest medical colleges, there is little scope for the development of powers and correction of foibles, which intercourse with our fellows ensures. In some, there are already strong corporate feeling and hearty comradeship; and these are elements which help to form an university. Our students well deserve that all possible should be attempted to give them the best instruction and the best education. The contrast between what they were thirty years ago and what they are now is too little appreciated. If, here and there,

"*Pauca tamen suberunt priscae vestigia fraudis*,"

these survivals will become more rare as our students enjoy more liberal instruction and freer intercourse. Even now, the average student in London works much better, and plays almost as well, as the average undergraduate in Oxford: he is not more ignorant, and is almost always unaffected.

Probably, the wisest way in which the Senate could improve medical education would be by leaving the smaller schools to arrange for co-operation (like the smaller colleges at Oxford), only insisting on certificates coming from teachers who have adequate time and appliances for teaching their subjects, and itself to undertake one or more of the advanced and less necessary branches of study. This would be for senior students who have passed the Colleges of Physicians and Surgeons, or have taken their Bachelor of Medicine degree. The Report to Convocation puts the importance of this class of studies very clearly in the following paragraph.

"No years are more precious or more often wasted than those which intervene between graduation and active employment in professional life. It is at this time that the mind, disciplined by sound training and stored with acquired knowledge, is best able to enter upon special departments of pure science, and to advance knowledge by mature study and independent research. To aid in this object, to detain the graduate *inter sitas academi*, and guide him in the pursuit of knowledge, seems peculiarly the office of an university as distinct from a college. Your Committee, therefore, believe that the Senate might with great advantage consider the advisability of founding university chairs in subjects, of which the following list may serve as an illustration: the higher mathematics; the critical study of classical authors whose works rarely form part of an examination or of a college curriculum; jurisprudence and public law; the history of medicine; public health and forensic medicine; certain departments of mental philosophy and ethics; of human and comparative anatomy; of pathology; of chemistry; or of physics.

"As examples of the kind of lectures meant, your Committee may refer to the Hunterian Lectures at the College of Surgeons, the Goulstonian and other lectures at the College of Physicians, and the Brown Lectures, which have already and with signal success been instituted by the Senate.

"It would be necessary, in order to reap the full benefit of such means of promoting the higher learning, for many of the lectureships to be provided with laboratories or museums or libraries; and in some cases these would be the primary and more important means of promoting the advance of the science, to which the lectures would form an useful adjunct as a means of exposition. Here, again, your Committee are happy in being able to refer to the solid results which have followed the wise audacity of the Senate in refusing to confine their labours to the superintendence of examinations, and accepting the responsibility of an endowment. The laboratory of the Brown Institution is a standing proof that it is only necessary to open a room where men can work, with very moderate and inexpensive aids, in order to call forth original research of the highest order."

This kind of work is just what ought to be expected of men who aspire to the higher university degrees of M.D., D.Sc., and M.S.

"There seems to be almost an absurdity in subjecting candidates for the degree of Doctor of Medicine (to take one faculty as an example) to a repetition of the same process of examination which they passed, perhaps with high honours, only a year before. The Senate have wisely introduced the important collateral branch of mental philosophy at this stage of the curriculum. But why not admit, as a qualification for the higher degree, some evidence that the Bachelor of Medicine has learnt to use his acquirements in the pursuit of fresh knowledge? The evidence of this power might be furnished by so humble but useful a piece of work as a statistical inquiry into some department of hospital records, or by the observation of some new fact in anatomy or medicine, or by devising an ingenious piece of apparatus or a new experiment; or the claim to the doctor's degree might rest upon discoveries of sufficient importance to be published in the *Proceedings of the Royal Society*."

The practice of requiring a formal thesis for the doctor's degree is one now out of fashion; but, from the experience of Edinburgh, Paris, and the German universities, it seems in some cases to do much good, and in most to do no harm. Even the poorest essay of the kind, if genuine, must be the fruit of a little thought and not a little reading; while a *thèse pour le doctorat*, on a subject given by a teacher to an

intelligent student, calls forth his powers, and awakens the desire of adding something to the store of common knowledge. Indeed, in not a few cases, such inaugural dissertations have been the germ of important later researches.

The resolutions, then, of Convocation, while pointing to a policy which would greatly increase the reputation and usefulness of the University of London, also suggest means of supplying what we believe to be the most important deficiencies in our medical education.

Even if what is now called the University of London did not exist, or if it were to refuse all functions of an university but that of examining, it would be none the less necessary to carry out the objects we have indicated. If further improvement in medical education can be connected with the development of the university in other branches of learning, the benefit will be doubled; for the more thorough, the more liberal, the more complete the education of our profession, the better, not only for it, but for the nation.

### THE NON-ALCOHOLIC TREATMENT OF DISEASE.

LORD ABERDARE presided on Thursday, May 30th, at an annual meeting of the London Temperance Hospital, which was established five years ago to carry out the non-alcoholic treatment of disease. The meeting was held in the Memorial Hall, Farringdon Street; and among those on the platform were Cardinal Manning, the Rev. Dawson Burns, Mr. Hugh Owen, sen., and Mr. Cash. Sir Wilfrid Lawson was absent through ill-health. The fifth report of the institution stated that the year's proceedings had in all respects been confirmatory of the conviction derived from previous experience—that the non-alcoholic principle of treatment was scientifically sound as it was morally safe. The in-patients' department had received 130 persons, making a total of 585 in-patients since the opening of the institution four years and a half ago. The out door patients had numbered 1,272, making a total of 5,478 in the same period. Of the in-patients for the year, 70 were males and 60 females; 85 had been abstainers, and 45 non-abstainers; 99 had resided in the metropolitan district, and 31 in the country. The medical and surgical cases of a severe and serious type had been quite equal to the average proportion in other hospitals, and such as, according to traditional usage, would have been treated with a liberal supply of alcoholic liquors; but the absence of these liquors had not been considered by the visiting physicians to have been attended with any disadvantage, but to have conduced to recovery or to an abatement of disease. It was pointed out that the year had yielded many evidences of the growth of medical and public opinion in favour of the non-alcoholic treatment of disease. Where alcohol was given, the quantity administered was often reduced; and how much could be done in this direction by medical officers, was shown by the facts published in regard to Longford, Wrexham, and many other places. A recent example was at Wandsworth and Clapham Union Infirmary, where the ounces of distilled spirits given in one week in 1877 amounted to 1,340, but fell to 320 in one week in 1878. The pints of porter and ale also given in the same week sank from 998 in 1877 to 658 in 1878. It was added that the suspicion awakened as to the superstitious value hitherto attached to alcoholic compounds could not but bear good fruit in the minds of enlightened members of the medical profession. Both the dietetic and medicinal use of alcohol had been recommended by its supposed power of increasing the sum of strength, and so tending to preserve health and to assist in its recovery. But belief in this notion was fast disappearing from thoughtful minds. Amid loud cheers, the words of Mr. Gladstone at the Coffee Taverns Company were quoted: "There is a general belief that alcoholic liquors tend to give greater bodily vitality; but I do not believe that there is a greater superstition than to suppose that these liquors can give men a greater capacity for bodily or mental exertion; and in this I am supported by the highest medical testimony." To this earnest declaration was added the sanguine hope of the committee: "The temperance reforma-

tion will receive from science that undivided help which will multiply its triumphs, and give to its operations a greater security and permanence than it has ever before enjoyed."

Lord Aberdare, in moving the adoption of the report, showed a sage reserve in declining to accept, upon the dicta of this report and of the officers of this hospital, the conclusion that disease either can be advantageously, or ought to be, treated in all cases without alcohol. He drew attention to the Declaration concerning Alcohol, signed by a great body of eminent medical men, which was originated some years ago with the late Dr. Parkes, Mr. Ernest Hart, and Mr. Rae, and which, being widely circulated and much discussed, subsequently had great effect in modifying the prevalent public errors concerning the supposed tonic and nutrient value of alcohol. The text of that weighty manifesto was authenticated by the signature of the great majority of leading physicians and surgeons in the metropolis and a large number throughout the country; and, as it is now frequently misquoted and overlaid with commentaries which are not strictly in accordance with its meaning, it may be useful here to quote it.

"As it is believed that the inconsiderate prescription of large quantities of alcoholic liquids by medical men for their patients has given rise, in many instances, to the formation of intemperate habits, the undersigned, while unable to abandon the use of alcohol in the treatment of certain cases of disease, are yet of opinion that no medical practitioner should prescribe it without a sense of grave responsibility. They believe that alcohol, in whatever form, should be prescribed with as much care as any powerful drug, and that the directions for its use should be so framed as not to be interpreted as a sanction for excess, or necessarily for the continuance of its use when the occasion is past.

"They are also of opinion that many people immensely exaggerate the value of alcohol as an article of diet; and, since no class of men see so much of its ill-effects, and possess such power to restrain its abuse, as members of their own profession, they hold that every medical practitioner is bound to exert his utmost influence to inculcate habits of great moderation in the use of alcoholic liquids.

"Being also firmly convinced that the great amount of drinking of alcoholic liquors among the working classes of this country is one of the greatest evils of the day, destroying more than anything else the health, happiness, and welfare of those classes, and neutralising to a large extent the great industrial prosperity which Providence has placed within the reach of this nation, the undersigned would gladly support any wise legislation which would tend to restrict within proper limits the use of alcoholic beverages, and gradually introduce habits of temperance."

The Temperance Hospital goes far beyond this manifesto in its principles and practice. Such an institution, established to maintain and not to test a view can never, according to all past experience, produce any results of scientific value. The experience of all the "homoeopathic" and "mesmeric" hospitals, and their flourishing statements, shows that very good reports may be obtained from the experience of all persons of extreme views in the treatment of disease. Clinical medicine is not yet, nor is there any apparent likelihood of its becoming, an exactly scientific art. The factors with which it has to deal are too complex and varying; and the subjects of observation, being suffering human beings, cannot be selected with the severity or submitted to the rigid conditions of experiment which scientific accuracy demands. We may be perfectly sure that in a temperance hospital, supported by total abstainers, very good results will be attained. But such results will do nothing, or if anything very little indeed, to settle the question of what is the place of alcohol as a stimulant in the treatment of disease. The experiment may serve to fix attention upon the fact that diseases of all types can be treated without alcohol and by the substitution of other stimulants. But it will furnish no solution to the problem whether we should do wisely to discard from our armoury one of the most valuable of medicinal agents on the ground that it is liable to abuse by persons in health. On the same ground, opium, morphia, chloral-hydrate, chloroform, and ether may be rejected. As a standing protest against the abuse of alcohol, and as a reminder of the exaggerated value sometimes attributed to alcohol, such an institution may have its uses. But we doubt whether it can expect a permanent

existence; and it is pretty certain that the scientific value of its records can never be great in settling the question of the use of alcohol in medical practice.

### THE CHANTRELLE CASE.

WE know that there are many estimable persons who object to the punishment of death for any crime and under any circumstances. While we respect their opinions, we must protest against the course which they frequently adopt when they appeal to the Home Secretary for the reprieve of a man convicted of murder by poison. They have taken up a theory that the punishment of death is not deterrent, and that it is useless as a means of protection for society. It would be easy to disprove this statement; but that is not our present object. We have to complain that medical witnesses and medical science are improperly made a scapegoat for criminals on these occasions. The facts are generally misstated, and the evidence is distorted, while the scientific witnesses are attacked as incompetent and their opinions pronounced to be untrustworthy.

The case of M. Chantrelle, recently tried at Edinburgh for the secret murder of his wife by poison, will serve as an illustration of these remarks. After a four days' trial, in which all the witnesses who could throw light upon the case were examined on both sides, and a most elaborate defence had been made by the counsel for the prisoner, the accused was convicted of the crime. It is true there was no direct evidence of the administration of poison by the hand of the prisoner but a number of circumstances conclusively pointed to his guilt. It was clearly demonstrated to the satisfaction of the Court, that the accused had the motive, the means, and the opportunity for perpetrating the crime, and that he further tried to conceal the act by a false pretence—a sure sign of conscious guilt. In secret murder by poisoning, direct evidence of administration, for very obvious reasons, can rarely be obtained; and if we wait for this kind of evidence before conviction, the most cunning and crafty criminals would escape the penal consequences of their acts.

The memorialists, in their address to the Home Secretary, allege: "That the prisoner is very poor, and, as a consequence, no medical evidence was adduced on his behalf at the trial, which would have been, as can now be shown, of signal importance, his counsel contenting themselves with a knowledge that the evidence as to opium-poisoning was so inadequate to convict that they did not go to the *expense or trouble to propose any theory of death from natural causes*. Nor was there a single medical expert on behalf of the prisoner at the *post mortem* examination, exhumation, inspections, examinations, or analyses, and that, notwithstanding these facts, your memorialists are firmly convinced that the case for the prosecution signally fails to show conclusive evidence of guilt."

We believe that the true reason why no medical evidence was adduced at the trial on the prisoner's behalf was really that the *post mortem* examination revealed no natural cause of death, and no medical man of repute could be found to take an adverse view of the evidence given on the part of the prosecution.\* The memorialists appear to think that had the prisoner had the means, "a theory of death from natural causes" might have been purchased. But the counsel for the defence showed greater wisdom. They foresaw that to call any medical man of repute—and none other would have served their purpose—would have been to ruin their case. Any honest expert by cross-examination would have been brought to agree with Drs. Littlejohn and MacLagan, and would have thus been converted into an additional witness for the prosecution. If, therefore, they failed in refuting the evidence of opium-poisoning, it was because it was too strong for refutation.

\* In another part of the memorial it is stated that "beyond the possibility of dispute, the case was one of undiagnosable kidney-disease," and that this was the natural cause of death. There was no reasonable foundation for this statement. The kidneys were not examined, except externally; and it is from this negative evidence that the memorialists infer that this disease existed and might have caused death.

We are told 'in the memorial that not a single medical expert was called on behalf of the prisoner. This is not strictly correct. Professor MacLagan was called on the part of the defence, and stated fairly in answer to questions all that could be said in favour of the accused. So again, Mr. Falconer King, city analyst, appeared as a chemical expert, and as we have elsewhere stated, endeavoured to throw a doubt upon the accuracy of the chemical evidence given by Drs. Littlejohn and MacLagan, in reference to the discovery of morphia and meconic acid in the opium stains on the night-dress of deceased. In his examination in chief, this witness said that stains of saliva, vinegar, and orange-juice, might be mistaken for opium. In his cross-examination, however, he simply confirmed the witnesses for the Crown, by admitting that he knew of no substance or mixture of substances but opium which, like these stains, would give the reactions of morphia and meconic acid.

Assuming the character of experts, the memorialists say: "We desire further to state confidently that the symptoms of dishevelled hair, tossing about of the bedclothes, and other appearances of agitation, even in this case, are inconsistent with opium-poisoning." They also state that the absence of clammy perspiration and stertorous breathing are always present in opium-poisoning. We deny the truth of this confident statement, from a case of opium-poisoning which fell under our observation.\*

One other point requires notice. We are told that the theory of opium-poisoning in no way accounts for the illness of the deceased on the previous day. This may be freely admitted; but it is quite possible that a person may be labouring under illness one day and be poisoned with opium the next.

We think we have shown, by this analysis of the statements in the memorial, that the attempt to raise a doubt in the minds of the public and the Secretary of State of the propriety of the conviction in this case, is based upon mis-statement or a misconception of the real medical facts, and it has been very properly rejected by the authorities.

The memorialists, however, are not contented with the effort to remove the charge of guilt from the convict; they insinuate that the opium-stains on the sheet may have been produced by the prisoner's mother-in-law, who had it in her possession for four days before it was submitted to analysis. We offer no comment on this suggestion, for which we cannot see that there is the slightest foundation.

The recently broken gas-pipe in the bedroom was considered by the prosecution to be a strong proof of guilt, but the memorialists have a theory to account for this consistent with the prisoner's innocence. When the accused found his wife in a comatose state, he believed that she would not recover; and in order to cheat the Accidental Death Insurance Company, in which her life was insured for one thousand pounds, he broke off the pipe to make it appear that she had died from gas-poisoning. A similar motive led him to persuade the medical attendant that the death of deceased was not due to natural causes, but to accidental gas-poisoning.

These efforts on the part of a few persons to mystify a clear case of murder have proved unavailing. On a future occasion, we think it would be better if memorialists would leave the medical facts and conclusions to be dealt with by members of the medical profession, and confine themselves to the general evidence.

At the dinner of the Victoria Hospital for Children, at Gough House, Chelsea, under the presidency of the Earl of Cadogan, it was stated that the hospital was wholly without endowment, and that since its establishment in 1866 it had relieved upwards of 3,040 in patients and 149,000 out patients, children from all parts and all denominations being admitted. The expenditure during the last twelve months was £434 in excess of the sum received. Subscriptions were announced amounting to about £1,000.

\* The daughter of an eminent chemist took by accident an ounce of laudanum. When seen, she was restless, restless, and tossing about the bed; the skin was hot, and there was no clammy perspiration or stertorous breathing.

THE Goldsmiths' Company have voted £500 to the Maintenance Fund now being raised for the support of the London Hospital.

THE Standing Orders Committee of the House of Lords declined to dispense with those orders in favour of the Manchester Water Bill—the Thirlmere scheme—which had not complied with them. The Bill is, therefore, at an end for this session.

A PETITION in support of the amendment proposed by Mr. Young, M.P., on the Dental Practitioners' Bill has been signed by most of the leading medical men in London. The object of the amendment is to prevent any one from using the title of surgeon, either alone or in conjunction with any other word or words, unless he is a surgeon or registrable under the Medical Act of 1858.

A BANQUET in connection with the Harvey Tercentenary was held at the Royal College of Physicians on Saturday, and about one hundred guests and fellows of the College dined together in the library. The chair was occupied by the President of the College, Dr. Risdon Bennett, F.R.S. Among the speakers were Professor Huxley, who pronounced an eulogium on Harvey, Lord Ripon, Mr. Gladstone, Mr. Lowe, Mr. Benett-Stanford, M.P., Dr. Allen Thomson, Dr. Quain, Dr. Michael Foster, and Mr. Birkett.

THE Ottoman Red Crescent Society for the relief of the sick and wounded Turkish troops has given notice to all the foreign surgeons in its employment whose contracts terminate at the close of this month, that those contracts will not be renewed. Most of these surgeons have served in various ambulances in Europe and Asia.

At a recent Committee meeting of the South Midland Branch of the British Medical Association, held at the house of the President (W. Moxon, Esq.), a testimonial in the shape of a handsome silver salver was presented to Dr. Bryan of Northampton, in recognition of his services as Honorary Secretary to the Branch for about twenty years.

We publish to-day the report, from the pen of Dr. Marion Sims, of an operation which is, we believe, unique. It is in every way highly interesting, and its teachings are likely to have an effect in showing that a class of cases of occlusion of the gall-bladder, hitherto considered beyond the reach of early surgical interference, may be attended with good hope of successful result.

THE interesting communication of Dr. George Harley is, it will be observed, printed, at the request of the author, in a peculiar orthography, which he has devised as a means of spelling reform, which aims at economy and simplicity in writing by the omission of "needless (or, as he spells it, 'needles') duplicated consonants". The suggestion is ingenious, and is well supported in a pamphlet on the subject, which Dr. Harley has published.

PUBLIC attention is just now naturally very much directed to the applications of that marvellously interesting magnifier of sound, the microphone, which, deeply interesting and valuable in itself, came so soon after the discovery of the telephone as to lead to the legitimate hope, that we are on the eve of a further great extension of our physical resources by the aid of scientific investigation and professional ingenuity. Our own profession is keenly alive to the possible application of these novel and remarkable physical instruments of research to physiological inquiry and clinical practice. We hear of large sums being offered to philosophical instrument-makers for the first trials of any instrument which makes the principle of the microphone applicable to stethoscopic examinations. Other applications are being made or attempted.

WE publish in another column a very interesting report, by Sir Henry Thompson, of the results of the clinical application of the microphone to the detection of stone in the bladder.

THE following communication appears also in the *Times* of May 31st, under the heading of Deafness and the Microphone. "Under the above heading, the writer of a letter to the *Times* of May 30th makes the following remark in speaking of those who are deaf: 'Science hitherto has done little or nothing for them, either in curing or in assisting hearing by instruments.' While fully alive to the truth of the latter portion of this statement, in justice to both English and continental surgery, I trust you will find space to allow me to question the correctness of the first portion of this sentence. The symptoms of deafness or blindness depend absolutely upon some change (the result of accident or disease) in either the conducting apparatus of the ear or the eye, or upon change (similarly produced) in the nervous portions of these organs. It may be accepted as a general truth that change in nervous structure is for the most part uninfluenced by treatment; but, in regard to the conducting portions of the ear, no less than in the case of the eye, it is well known to surgeons that the treatment of change in these parts has made during the past few years very considerable advances, and that diseases which twenty years ago were regarded as irremediable are at the present time treated most satisfactorily. It is now gradually but surely becoming appreciated that the success derived from surgical interference in affections of the conducting portions of the ear is no less certain in this than in other structures of the body, and that the same rule holds good in these as in other diseases—viz., that whenever abnormal tension is the cause of disorganisation, the results to be expected from treatment vary directly with the period at which treatment is commenced. It remains only for me to add that the application of the microphone as an aid to incurable cases is now under investigation.—I am, sir, your obedient servant, W. B. DALBY, Aural Surgeon to St. George's Hospital."

SIR THOMAS WATSON has published, in the *Nineteenth Century*, a paper on "Small-pox and Compulsory Vaccination", in which he advocates the return to vaccination from the heifer, or at least to a renewal of vaccine lymph by the introduction of fresh sources of calf-lymph from time to time. We confess, however, that his paper is far from being so carefully studied as Sir Thomas Watson's productions usually are; and we cannot but think that it would be advisable that he should have given some further attention than he has done to the grave doubt which investigation has thrown over the alleged good results of calf-vaccination in Belgium and Russia, to which he refers as though they were facts undoubtedly proved. The subject is one of such very serious importance, that anything like hasty conclusions drawn from insufficient grounds are very greatly to be deprecated, especially when such conclusions are expressed by so eminent and respected an authority as Sir Thomas Watson in a popular publication.

MR. SIBLEY, President of the Metropolitan Counties Branch, received the members at a *soirée* on Wednesday last. A very pleasant evening was spent. Numerous objects were exhibited, among which were the telephone, microphone, and phonograph, the operation of which was witnessed with great interest.

FOR many years, the hospital transport ships which return to France from Saigon have, say the French medical papers, sown the route with dead bodies. The average deaths were twenty for each ship. The transport ship *Aveyron*, which arrived at Toulon on April 20th, had not a single death; this result was due to the employment of the precaution against dysentery recommended by Dr. Dounon. This consisted in nothing else than the well known method of boiling the drinking water, so as to transform into inert matter the anguillulæ which, by fixing themselves on the intestinal mucous membrane, give rise to dysentery, etc. The efficacy of boiling in destroying active animal and vegetable parasites is well known; and according to Dr. Dounon, dysentery is always caused by the introduction of contagia into the body by drinking water; and the hope is expressed that that fatal disease may in all countries be suppressed by the adoption of this very simple precaution.

#### BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.

THE annual meeting of this Society was held at the Medical Institute, Birmingham, under the presidency of Alfred Freer, Esq., of Stourbridge. The report of the Society showed that there were thirteen annuitants, and that £445 had been expended in grants during the past year; that there were two hundred and thirty-eight members, thirty-one of whom had been elected during the past year. The following officers were appointed. *President*: Mr. Watkin Williams.—*President-elect*: Dr. J. J. Nason, Stratford-on-Avon.—*Vice-Presidents*: Mr. T. Elkington, Fenny Compton; Mr. J. Garner, Birmingham.—*Honorary Secretary*: Mr. T. H. Bartleet, Birmingham.

#### LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

THE annual general meeting of this Society was held lately at the Leeds General Infirmary; Mr. Scattergood (the President) in the chair. The Committee, in presenting the sixth annual report, congratulated the members of the Society on its continued prosperity. At the last annual meeting, the number of members was one hundred and eighty; since that time, two members had died, four members had resigned, and ten had left the neighbourhood. On the other hand, fifteen new members had been elected, so that the present number was one hundred and eighty-three. Eight ordinary meetings had been held during the last session, and had been, as usual, well attended. The May meeting was devoted to a discussion upon typhoid fever: this was so successful that the Committee hoped to be again able to devote a whole evening to the discussion of some one subject of general interest. The following gentlemen were elected office-bearers for the ensuing year. *President*: Dr. Holdsworth (Wakefield); *Vice-Presidents*: Mr. Pridgin Teale and Mr. Hodgson Wright (Halifax); *Treasurer*: Dr. Heaton; *Honorary Secretaries*: Mr. McGill and Dr. Churton; *Librarian*: Mr. Horsfall; *Committee*: Dr. Clifford Allbutt, Mr. E. Atkinson, Dr. J. H. Bell (Bradford), Dr. Eddison, Dr. Ginders (Normanton), Mr. Lodge (Bradford), Mr. Nunneley, Mr. Seaton, Dr. Symes (Halifax); Dr. Tibbits (Bradford), Mr. T. Walker (Wakefield), and Mr. C. J. Wright. The meeting terminated with a vote of thanks to the Chairman.

#### POISONOUS VIOLET POWDER.

AT the Epping Petty Sessions, on Friday, May 31st, Henry George King, wholesale chemist, again appeared to answer the charge of having caused the death of Eliza Sears and others, and further with having unlawfully and fraudulently sold violet powder containing large quantities of arsenic, to the danger of the public health. Mr. Poland prosecuted, and the prisoner was undefended. Evidence was adduced to show that many children had died after the employment of the violet powder upon their bodies. The defendant said, as soon as he heard of the facts, he tried to stop the sale of the powder, which was being sold all over London. Mr. Poland admitted that the defendant had done his best to restrict the sale of this powder, and hoped that he would give the names of his customers, so that the powder might be traced. The defendant said he wished to do so. He hoped the newspapers would publish the facts, that people might be warned. Dr. Dap of Westminster Hospital stated the percentage of arsenic, ranging from fifteen to fifty-one, found by him in the packets submitted to him for analysis. He had examined two packets taken from the defendant's premises, and both were free from arsenic. He also received a packet of terra alba, which was free from sulphate of lime and contained no trace whatever of arsenic. Mr. Barnard Thomas, of the Treasury, had handed him a packet of violet powder, one of those seized by Sergeant Roots in Cambridge Road on Monday, and, on testing it, he found it to contain a great percentage of poison. Anyone accustomed to deal in starch and terra alba could easily distinguish them from arsenic, which was a dull, not white, powder. Terra alba was more white and opaque. Powders mixed with 30 per cent. of arsenic ought easily to be recognised by persons dealing in such things; in fact, they could distinguish the difference with the eye and with the hand, as there was a great difference in the weight. The symptoms described by the

witnesses were similar to those which followed the application of arsenic to the skin. He knew that there were cases recorded in which death had ensued from outward application of arsenic. Fly-papers and insect-powders, which were amongst the list of articles sold by the defendant, might contain arsenic. The case was again adjourned.

#### MEDICAL SERVICE AT ST. PAUL'S CATHEDRAL.

A SPECIAL service for the medical profession was held in St. Paul's on Friday last; and, if numbers may be taken as any test, it should be pronounced a great success, between four and five thousand people being present, amongst whom were many well-known members of the medical profession. The musical part of the service was ably rendered by the vocal and instrumental choirs of the London Gregorian Choral Association, who numbered in all about four hundred; the congregation joining very heartily in the service. The office was sung by the Rev. Minor Canon Shuttleworth. The Rev. Henry Arnott, F.R.C.S., formerly on the staff of the Middlesex Hospital, but now in deacon's orders, was in the choir. The first lesson was read by the Rev. George Greenwood, M.A., Warden of the Guild of St. Luke; the second by the Rev. T. W. Belcher, M.D., D.D., Vicar of St. Faith's, Stoke Newington. The sermon was preached by the Rev. George Body, M.A., on the Ascension. The idea of the service originated, we are informed, with the Guild of St. Luke, a society of students and practitioners of medicine; it has for its Provost Dr. Alfred Meadows. The objects of the guild are "to encourage the growth of personal holiness in its members, and to promote works of mercy, etc." Meetings are held on the third Wednesday in each month for the discussion of medico-ethical questions and others bearing on the relation of the clerical and medical professions. At its next meeting on June 19th, which will be held at 68, Mortimer Street, at 7.45 P.M., the subject for discussion is a paper by J. W. Lea, Esq., B.A. Oxon., on the Suppression of Immorality from a Medical Point of View. Members of the profession are invited to attend and take part in the discussion, which will be chiefly on the medical aspect of the question.

#### PROVIDENT DISPENSARIES.

THE movement in favour of the extension of provident dispensaries is daily assuming a wider importance. There can be little doubt that the conversion of all free dispensaries to the provident system is merely a question of time. The medical officers attached to free dispensaries are becoming sensible of the injustice of having to give their services gratuitously, while their more favoured brethren on the staff of institutions on the provident footing annually participate in a good lump sum subscribed by the benefit members. In every class, a fair day's work can only be expected for a fair day's wage—"The labourer is worthy of his hire".

#### THE IMMUNITY CONFERRED BY REVACCINATION.

THE immunity from small-pox enjoyed by the medical officers, nurses, and others employed in small-pox hospitals affords one of the most powerful arguments in favour of adult revaccination as a protection from small-pox. No more satisfactory or conclusive statistics bearing upon this point have ever been published than those contained in a recent report, by Dr. William Gayton, the Medical Superintendent, upon the work done in the Metropolitan Asylum Small-pox Hospital from its opening on 1st February, 1871, to 31st December last. The Registrar-General reproduces some extracts from this report in his last weekly return, and supplements it with some additional information supplied by Dr. Gayton. During the period of nearly seven years, the number of nurses and others who have at various times been engaged in this hospital is not less than 367. Revaccination has been an indispensable condition of employment, unless the applicant had had small-pox, or had been revaccinated previously to application. The result of these precautions is thus described by Dr. Gayton: "That not only amongst the large number of nurses and others who have been occupied here (and in her case the operation was neglected) should have contracted the disease is, or should be, convincing proof of its great

and almost certain prophylactic influence." It is impossible to over-estimate the value of this evidence, which, in the Registrar-General's words, "cannot be too generally known". That adult revaccination affords all but absolute protection from small-pox, no one with this evidence before him can reasonably doubt; for in these hospitals the nurses and others are brought into contact with the most intense and virulent forms of the disease. While the expediency of making revaccination compulsory may well be doubted, there can be but little doubt that our national vaccination system should not only offer greater facilities for revaccination, but systematically encourage its more general adoption.

#### SMALL-POX IN KENSINGTON.

DR. DUDFIELD reports a severe outbreak in the south sanitary division of his district, and states that he believes the disease to have been spread to a great extent by concealment of cases at home. He instances a laundress who was seen by a local practitioner on the day she sent home a large quantity of washing, when the eruption was "well out upon her". Another laundress was nursed at home by her husband and the business carried on during the whole time, although there were sixteen lodgers in the house, all of whom left, and probably spread the disease broadcast amongst the inhabitants. He mentions another case of a lady's-maid, who alone was attacked out of a large household; and, as she scarcely ever went out, the cause could not be discovered. After a time, it was found out that a sempstress who came to the house had had two children ill of this disease, but escaped it herself. Dr. Dudfield alludes to the refusal of revaccination by adults and their subsequently contracting small-pox, which has frequently happened in this epidemic. The necessity for revaccination amongst the poorer classes especially seems to be almost utterly ignored, and should be earnestly urged upon every one in a house where the disease breaks out. Too much pains cannot be taken in pressing upon those who have been exposed to the infection of small-pox the importance of immediate revaccination.

#### LEAD-POISONING BY FLOUR.

WE recently published a notice of a rather serious epidemic of lead-poisoning in the Taunton Sanitary District in consequence of the holes in millstones having been filled up with lead. The practice appears to be not confined to this country. In the last number of the *Nordiskt Medicinskt Arkiv* is a paragraph taken from a Norwegian periodical, in which it is stated that Dr. O. Johnsen of Sarpsborg had met with an extensive endemic of gastric disorder, often accompanied with diarrhoea, for which he could find no cause in the local conditions, nor was there any evidence of contagion. The lead-line on the gums was detected; and it was ascertained that the flour which the patients used had been procured from a mill, the owner of which had filled up the holes in the millstones with a mixture of whitelead and glycerine. There were no cases of paralysis or of brain-disease; and the patients, with the exception of one who died, all recovered. A similar occurrence is reported to have taken place in France from the use of lead to repair millstones.

#### TYPHUS AND SCARLET FEVER AT LEEDS.

BOTH these diseases have lately been prevalent at Leeds; indeed, Dr. Goldie says that he despairs of ever seeing the town free from scarlet fever, as he does not receive sufficiently early information of outbreaks. He also states that he has known infected houses let without proper precautions having been adopted; "that infected beds are sold and pawned which are innocently and eagerly purchased at a small figure, the purchasers receiving more than they bargained for". The typhus cases appear to have been very malignant, as in one family not only none escaped, but even visitors were attacked, and the disease was only checked by removal to the hospital. Dr. Goldie also notices a considerable excess of deaths from inflammatory diseases of the lungs, owing to the prevalence of cold easterly winds. The importance of early information being given to the sanitary department of cases of

infectious diseases may be felt, but is practically ignored; and it is only by repeatedly pointing out the injury resulting from concealment of these cases that medical officers of health can obtain what they desire.

#### ACCIDENTAL POISONING.

AN inquest was held on May 29th at West Barkwith, before Dr. Mitchinson, coroner, on the body of Charles Pacey, aged two years. On the previous Monday, the child drank from a medicine-bottle on the table, which the mother believed to contain a solution of quinine. This had been given to her some time previously by the clergyman's wife (Mrs. Thompson), when she was suffering from debility. The child became ill and died. Dr. Harrison, who was called in, took possession of the bottle from which the child was supposed to have taken the poison, and telegraphed to the London chemists (Messrs. Keene and Ashwell of New Bond Street) who had prepared the medicine for Mrs. Thompson. In reply, they informed him that it was a solution of strychnine which had been furnished to a lady six or seven years ago. The jury returned a verdict that the child died from the effects of strychnine-poisoning taken accidentally, and that no blame was to be attributed to the mother; but at the same time they wished to express their strong dissatisfaction that the chemists should have sent out so strong a poison without putting a poison-label upon the bottle. Mrs. Thompson was under the impression that it was simply a solution of quinine. Several persons appear here to be in fault. The practice of handing about medicine from one person to another, without any adequate knowledge of the contents of the solution or its suitability for the individual, is in itself reprehensible. On the other hand, it is wrong to dispense such a medicine as that described in the present case without a very strong indication of its poisonous character; and, in our opinion, not only should the word "poison" always be very clearly inscribed, but such solutions should only be dispensed in coloured fluted bottles.

#### SIR EVERARD HOME AND INTRA-VENOUS INJECTION.

WITH regard to the statement in the JOURNAL of May 18th, in reference to Sir Everard Home injecting into the circulation sixty drops of the vinous infusion of colchicum, Mr. Richard Jones of Leamington writes: "I was a pupil of Sir Everard Home in the years 1818 and 1819; and I most unhesitatingly assert that he never made any such communication to his pupils as the *Pittsburg Gazette* describes. I have little doubt that the mistake has arisen from his taking colchicum as a medicine for gout, to which he constantly had recourse. I need hardly add that an experiment so novel and so important as that of transfusing medicine into the blood would never have been forgotten by the pupils, or otherwise regarded by the profession than a discovery only second in importance, as the *Chicago Journal* very justly observes, to that of the immortal Harvey."

### SCOTLAND.

AT a recent meeting of the Town Council of Jedburgh, a letter was read from the factor of the Marquis of Lothian, intimating that the Glebe Park could now be taken possession of by the provost and magistrates for the use of the inhabitants as a public park, at a nominal rent of one pound *per annum*. There was great rejoicing in the town at the announcement of this munificent gift.

#### EXECUTION OF M. CHANTRELLE.

THE sentence of death pronounced three weeks ago upon M. Chantrelle, for the poisoning of his wife, was carried into effect on Friday, May 31st, within the precincts of the Calton Prison, Edinburgh. Immediately before the execution, the convict was asked if he had any acknowledgment or statement to make; to this he quietly replied in the negative. He has left no confession. This case is the only one in which a person of education has been executed in Edinburgh during the last fifty years for a crime committed in the city. Pritchard was tried and condemned in Edinburgh for murder committed in Glasgow, but

his sentence was carried out in the latter city. Another notable fact, which is stated on good authority, is that, in no trial for murder by poisoning, was there ever before in Edinburgh an unanimous verdict of guilty.

#### ENTERTAINMENT AT ASYLUMS.

AT a recent meeting of the Barony Parochial Board, Glasgow, a report on the Lenzie Asylum was read. After speaking of the good management of the establishment generally, and stating that stimulants are little used, it went on to say: "A remarkable exception, however, is found from the entries of last month. The Committee gave an 'entertainment to the patients', and on the occasion, drew from the dispensary stores, and within a few hours used for themselves and friends no less than thirty-four bottles of whiskey, a quantity equal to the ordinary medical requirements of the whole establishment for some months. The whiskey is entered as used for the patients, and converts the five bottles really so used during the month into thirty-nine bottles. Such practices go far to degrade parochial management." The report was adopted. It was stated in the minutes of the Medical Committee, that during the month of April, nine hundred and twenty-seven cases been treated by the medical officers of the Board, being a decrease of twenty-one as compared with the previous month.

#### PRECOGNITIONS AND MURDER TRIALS IN SCOTLAND.

A RETURN ordered by the House of Lords, on the motion of the Earl of Minto, has been issued showing "the number of cases of sudden death, or of death under suspicious or unknown circumstances, which have been the subject of precognition by Procurators-Fiscal, in each of the years 1875 and 1876, and in which the investigations were from the first connected with charges of murder, culpable homicide, etc.; also specifying the number of such cases as have afterwards become the subject of criminal trials." From this return, it appears that the total number of such investigations in 1875 was 88, relating to 97 deaths; and that the total number of criminal trials consequent on the investigations was 54. In 1876, the number of investigations was 92, relating to 99 deaths, and 48 criminal trials resulted. As might be anticipated, the largest number of investigations and trials was in Lanarkshire, where in 1875, there were 27 investigations and 18 trials; and in 1876, 17 investigations and 8 trials. In Edinburgh, there were, in 1876, 10 investigations and 6 trials; in Stirling, 9 investigations and 5 trials; in Forfar, 7 investigations and 5 trials; in Aberdeen, 11 investigations and 4 trials. In other counties, the numbers were smaller; and in Argyll, Berwick, Bute, Clackmannan, Dumfries, Haddington, Kinross, Kirkcudbright, Nairn, Orkney, Peebles, Shetland, and Sutherland, there were no trials at all.

### IRELAND.

TWO members of the profession died last week at advanced ages, viz., Dr. Henry Pentland of Kells, county Meath, aged 75; and Dr. James Heffernan of Limerick, who was in the seventy-second year of his age. Both gentlemen were graduates in medicine of the University of Edinburgh.

#### RATHFARNHAM AND WHITECHURCH DISPENSARY.

AT a meeting of the Dispensary Committee held last Monday, to elect a medical officer to the district in the room of Dr. Henry Croly, who had resigned, Dr. Albert Croly was unanimously appointed. A resolution to allow superannuation to Dr. Croly senior, after his long and arduous services, will shortly be brought before the Committee.

#### ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

THE thirty-sixth annual meeting of the friends of this estimable Society was held on last Monday, June 3rd, at the College of Physicians, the chair being occupied by Dr. Samuel Gordon, President of the College. The total number of applications this year was ninety-seven; thirteen

being from medical men, seventy-two from widows, and twelve from orphans. Five of these were refused, four being orphans who were over age, and one case which was not considered as deserving of relief. In the interval between the last general meeting and the present, the central committee were obliged to make grants to thirteen cases of great urgency, amounting to £208. The money allotted among the ninety-two eligible claimants on the Fund this year amounts to £1,332 10s.; and in the following proportions: To medical practitioners, £457 10s.; to widows, £762; and to orphans, £113. Donations were received during the year amounting to £305, including £100 from Dr. Hudson, and a similar sum from that gentleman's brother; and it is satisfactory to learn that the receipts for the year derived from interest and subscriptions will be more than sufficient to pay the sums allotted. Dr. Magee Finny, having resigned the honorary treasurership, which office he filled for the past five years, has been replaced by Dr. Fleetwood Churchill. The report referred to the vitality and efficiency of the Society's branches in the East Indies, which remitted, during the past year, subscriptions amounting to £188. After the report had been adopted, a discussion took place as to the propriety of continuing to fund the donations and bequests of the Association; and eventually it was resolved, that in future they should be either funded or distributed at the discretion of the Managing Committee for the time being, unless in cases where otherwise specified. Votes of thanks to the honorary officers, and to the medical students who had contributed to the funds of the Society, having been passed, the committee and officers for the ensuing year were elected, and the proceedings terminated.

#### HEALTH OF BELFAST.

THE report of Dr. Browne, Medical Superintendent Officer of Health, brought before the Belfast Town Council last week, shows that, during the four weeks ending May 25th, the deaths from zymotic diseases amounted to 40, a number considerably below the average. The death-rate, although still high, being 25.18 per 1,000 on the corrected population, has arisen from the amount of diseases of the respiratory organs caused by the variable weather. Dr. Browne states that he is unable to trace the cause of the late sudden outbreak and spread of small-pox; but he believes that the constant communication which prevails among the humbler classes, between the healthy and the sick, without any precautions being observed, fosters the infection and spread of contagious diseases to a lamentable extent. He urges the necessity of vaccination and revaccination, as, although the present epidemic of small-pox has not hitherto been of a violent type, as manifested by the comparatively light mortality, no one can foresee when it may assume a more malignant form: hence the entire community should endeavour, by every means in their power, to aid the medical profession and the sanitary authorities in their efforts to stop the spread of and eradicate this loathsome disease.

#### ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual meeting of the Fellows of this College, to elect a President, Vice-President, Council, and Secretary, for the ensuing year, was held on Monday last. Philip C. Smyly, M.D., Surgeon to the Meath Hospital, was elected President; Edward D. Mapother, M.D., Surgeon to St. Vincent's Hospital, Vice-President; William Colles, M.D., Secretary; and the following nineteen Fellows Councillors, viz.:—William Colles, Alfred H. McClintock, George H. Porter, George H. Kidd, Benjamin G. McDowell, William A. Elliott, T. Joliffe Tufnell, Edward Hamilton, Edward Ledwich, Rawdon Macnamara, Robert McDonnell, F.R.S., John K. Barton, Archibald H. Jacob, Henry Gray Croly, John Denham, Anthony H. Corley, Benjamin F. McDowell, William Stokes, and Samuel Chaplin. It will thus be observed that the outgoing Council, with the exception of Mr. Albert Walsh, were re-elected; the vacancies on it being filled up by the election of the retiring President and Messrs. H. Gray Croly, Elliott, and A. H. Jacob. There was some canvassing carried on before and during the time of the election, which was very reprehensible, and has caused much comment.

#### THE MEDICAL ACTS AMENDMENT BILL.

WE are informed that the Medical Reform Committee of the British Medical Association has decided that the Bill of the Association should be introduced in the House of Commons, in consequence of the Lord President's Bill, as then before them, not enforcing the conjunction of the universities with the corporations, and not including direct representation. It was arranged to do this, and the Bill was introduced on Wednesday May 29th, before the Chairman received the newly printed and amended Bill of the Lord President.

The Duke of Richmond and Gordon received, at the Privy Council Office, on Friday afternoon (May 31st), a deputation representing the London School of Medicine for Women, and those ladies who, as registered medical practitioners, had already petitioned against the Bill. The deputation, consisting of Mrs. Thorne, Mr. A. T. Norton, Dr. Garrett Anderson, Dr. Louisa Atkins, Dr. Sophia Jex-Blake, and Dr. Ann Clark, was introduced by Lord Aberdare, who stated to the Lord President the wishes of those present. They were anxious, he said, to ascertain whether it was intended that both the examinations and the diplomas under the Bill should be identical for all candidates of both sexes who presented themselves to the conjoint board; and especially they desired to know whether it would be in the power of any medical corporation to create an invidious distinction between those men and women who had passed the examinations with equal success, by bestowing different diplomas upon them without further examination. He pointed out that at present those women who were on the *Medical Register* had passed the ordinary examinations and received the same medical titles as their male competitors. The Duke of Richmond and Gordon said, in reply, that the Government had no intention of making any difference between the professional examinations and status of candidates, and pointed out that the Bill expressly provided that if any distinctions were made in the examinations, they should yet "guarantee equal proficiency". He would, however, consider whether it might be feasible to omit from the Bill all mention of possible distinctions in examination. With regard to diplomas, he further stated that it was distinctly the intention of the Government that these should be granted to all alike, and he did not consider that, under the Bill, it would be in the power of any corporation to refuse to grant to women the same diploma that they granted to men after examination by the conjoint board. After a few remarks from Dr. Jex-Blake, Dr. Anderson, and Mr. Norton, the deputation thanked the Duke of Richmond and Gordon for his assurances, and withdrew.

#### PARLIAMENTARY BILLS COMMITTEE.

At a meeting of the Committee held at the offices of the Association on June 3rd, 1878, there were present Mr. Ernest Hart (in the Chair), Dr. A. P. Stewart, Mr. Sibley, Dr. Grigg, Dr. Bryan, Mr. Nicholson, Mr. Walter Rivington, Mr. Tomes, Mr. Donald Napier, and Mr. J. H. Craigie.

*Army Medical Department.*—The Chairman made a report to the meeting of communications which had been made to the War Office during the last three months, on the subject of the improvement of the position of army medical officers in reference to the Committee at present sitting to consider the steps necessary for restoring popularity to this department. He laid upon the table a brief statement, summarising the present grievances and disadvantages of officers in the department, which had been submitted to medical officers of various grades, and met with general approval. Copies of this had been officially forwarded to the Secretary of State for War, and by him submitted to the members of the War Office Committee. It had also been placed in the hands of members of Parliament who had interested themselves in the subject, especially Mr. Lyon Playfair, Mr. Meldon, Dr. Lush, and Dr. O'Leary. A motion on the subject had been put on the paper of the House of Commons by Mr. Meldon; but the discussion upon it had been postponed, at the request of the Secretary of State for War, until after the conclusion of the investigation by the Committee. Dr. O'Leary had also proposed to call the attention of the House to the subject, and had been in communication with Mr. Ernest Hart; but, at the request of Lord Cranbrook, he had likewise postponed parliamentary proceedings. Meantime the War Office had addressed to the Chairman of the Parliamentary Bills Committee of the Association a schedule of questions relating to the estimated average emoluments of civil practitioners. A copy of this schedule had been forwarded to all the members of the Committee and to the Secretaries of the Branches of the Association. Thirty answers had been re-

ceived, of which twenty-seven contained approximate estimates, according to the opinions of the writers. In most instances, however, those estimates were accompanied by letters pointing out the uncertainty of the data. A tabulated analysis of the replies was laid upon the table. Dr. Stewart and other members of the Committee discussed the question; and a general opinion was expressed that, as absolute data were altogether wanting for replying with accuracy to the queries issued by the War Office Committee, and as such data might be found with more accuracy in the income-tax returns, a suitable letter should be addressed to the Assistant-Secretary at the War Office, giving a view of the returns furnished, but pointing out that they were necessarily wanting in positive data, and referring to the income-tax returns as being more reliable; at the same time intimating that such financial data were not themselves likely to be returned as materials for satisfying the claims of the army medical officers to moral as well as material amelioration of their condition. The schedule of questions from the War Office and the statement of grievances have already appeared in the JOURNAL.

**Factory Acts' Amendment Bill.**—The Chairman reported that the Factory Acts' Amendment Bill, in respect to which this Committee had taken part in the deputation to the Home Secretary with the Certifying Surgeons' Association last year, had been again introduced into Parliament this year; and that, in accordance with the views expressed last year as to the desirability of supporting the Certifying Surgeons' Association in advocating the amendment of the Bill, he had taken active measures to procure Parliamentary support in the amendment of the Bill. Early in February, he had received urgent communications from Dr. Arlidge, the President of the Certifying Surgeons' Association, and, in concerting with him, had arranged to press amendments aiming especially at the improvement of the fee for certifying, and the amendment of certain clauses which proposed to exempt factories employing less than ten children from inspection by the certifying surgeon. These proceedings had involved a considerable amount of trouble. Mr. Cross had, however, intimated to Mr. Lyon Playfair and to Dr. Cameron that, if the desired amendments were previously submitted to him, together with the reasons for them, he would consider how far he could give way on the subject. A tea-room meeting of members of the House of Commons had been arranged, and ultimately the Secretary of State had consented to remove the exemption to the smaller factories from inspection, but had refused to give way on the subject of the sixpenny fee. An attempt was made to induce him to alter this decision in the House of Commons, but this did not succeed. The amendments proposed by Mr. Lyon Playfair on behalf of the Committee had, however, been accepted. So far, the Parliamentary action of the Chairman on behalf of the Committee had been attended with important success. Letters of thanks were read from the Chairman of the Certifying Surgeons' Association and from the Secretary of the Certifying Association of Scotland, expressing their sense of the value of the energetic exertions which had been made on their behalf with a certain measure of success. A very voluminous correspondence relating to the subject was laid on the table.

**Coroners' Courts.**—The minutes of the Subcommittee on the Coroners' Court were read and confirmed, and printed papers were presented, including memoranda from Dr. A. S. Taylor, Dr. Hardwicke, Dr. Ferrier, Dr. Southey, and others, together with a considerable correspondence relating thereto. It was reported that, the Subcommittee having been informed that a Bill on the subject was in preparation at the Home Office for the purpose of bringing about improvements in coroners' investigations, the materials collected by the Committee had been forwarded to the Home Office for the consideration of the Home Secretary, with the request that the Committee might be informed of the purport of any intended legislation, and that some suggestions indicated by Dr. Hardwicke and Dr. A. S. Taylor should have the special consideration of the Home Secretary; and further expressing a desire to be allowed to confer with the authorities employed in drafting the Bill at a suitable stage. Communications were read from the Under Secretary of State, thanking the Committee for the information afforded, and promising that full consideration should be given to the documents and views submitted.

**The Irish Public Health Bill.**—Copies of communications from Dr. Grimshaw, Chairman of Council of the Irish Medical Association, relating to the Public Health (Ireland) Bill, and from Mr. Meldon, M.P., on the same subject, were laid before the Committee; and it was resolved to assist the Irish Medical Association in bringing forward desirable amendments in that Bill for improving the medical supervision and sanitary districts, and for appointing inspectors in connection with the Local Government Board of Ireland.

**Dental Practitioners' Bill.**—Sir John Lubbock's Bill, as amended, was laid upon the table; and the Chairman stated that, in pursuance of

the resolutions passed at the last meeting of the Committee, he had communicated with Dr. Cameron, M.P., who had interposed to prevent the passing of that Bill through committee, on the ground that it deprived registered medical practitioners of the power of practising as dentists, unless they had a special dental licence; and also that it proposed to give the title of dental surgeon to persons registered under the Dental Act, who also might not be members or licenates of any college of surgeons. Sir John Lubbock had accepted the amendments proposed in respect to the first matter, and had reprinted the Bill as amended by him to meet that view, giving all practitioners registered under the Medical Act full privileges of dental practice. Mr. Hart wished to consult the Committee as to whether they would desire to continue their opposition to the Bill, on the ground that it still proposed to allow the title of "dental surgeon" or "surgeon-dentist" to persons not members of any college of surgeons. With the view that the Committee should hear the arguments on both sides, he had invited Mr. Tomes, who had supported the Bill, and Mr. Donald Napier, who expressed the opinions of those opposed to it. The Bill was supported by Mr. Tomes, Dr. Stewart, and Mr. Sibley. Objections to the use of the title of dental surgeon, under the circumstances stated, were expressed by Mr. Napier, Mr. Rivington, and the Chairman. Dr. Grigg moved that the title of surgeon, under any circumstances, should be limited, in the opinion of this Committee, to persons who were members of a College of Surgeons. The motion was seconded by Mr. Rivington. Being put to the vote, it was lost, whereupon it was moved by Mr. Sibley, seconded by Dr. Stewart, and carried, that this Committee approves of the Dental Practitioners' Bill as now amended.

### IRISH MEDICAL ASSOCIATION.

THE annual general meeting of this Association was held in the Royal College of Surgeons on Monday last. Several of the members of the Association breakfasted together in the morning at the Shelbourne Hotel, under the Presidency of Dr. Grimshaw, Chairman of the Council. In the unavoidable absence of Dr. Darby of Bray, the President of the Association, Mr. Nolan of Gort, one of the Vice-Presidents, took the chair at the general meeting. The report of the Council was read by the active Honorary Secretary, Dr. Chapman; and, as showing the watchful interest which this body takes in behalf of the profession in Ireland, we may mention that the Committee of Council, upon whom most of the business of the Association devolves, held forty-seven meetings during their year of office. The chief subjects alluded to in the report were the Public Health (Ireland) Bill; the Medical Act (1858) Amendment Bill; the Amendment of the Vaccination (Ireland) Laws; the Registration of Births and Deaths, etc.; the Poor-law Union and Workhouses Amalgamation Inquiry Commission; Medical Witnesses at Coroners' Inquests; Superannuation to Medical Officers; etc. Only twelve new members joined the Association during the year. In addition to the customary resolutions on these occasions, and resolutions forming the Association into a registered and incorporated company, and adopting amended "objects and rules" of the Association as drawn up by the Council, the following were unanimously adopted by the meeting.

"That, whilst it would be an act of justice to the medical officers holding appointments in the Poor-law service, it would also tend to the benefit of the public, that such of those officers who, through illness or infirmity, have become unfit to discharge their public duties, or who, having either served twenty years or attained the age of sixty years, should be entitled to claim superannuation allowance, in amount not less than two-thirds of all their official emoluments.

"That the indiscriminate issue of tickets for dispensary medical relief which now prevails not only occupies unfairly the time of the medical officers, but also greatly and improperly increases the expenses of the poor-rate. This Association, therefore, approves of the propositions put forward by the Council in their communication addressed to the Poor-law Inquiry Commission on this subject.

"That it would be but just to the medical officers holding Poor-law appointments, and would tend towards increasing the efficiency of the service, that they should be entitled to a reasonable period of leave of absence in each year, as in the case of civil servants; and that provision for the same should be made at the public expense.

"That this Association approves of the action taken by the Council, concerning the Medical Act (1858) Amendment Bill now before Parliament, with reference to direct representation of the members of the profession on the General Medical Council, and also with reference to uniformity of education and examination for granting medical qualifications.

"That this Association approves of the action taken by the Council

concerning the Amendment of the Public Health (Ireland) Bill, and also approves of their action with regard to the Bills suggested by them to Amend the Vaccination Laws, and the Registration of Births and Deaths (Ireland) Act; and hereby directs that the Council shall continue their efforts to have these reforms carried into effect."

The following is a list of the officers of the Association elected for the ensuing year. *President*: Dr. Robert McDonnell, F.R.S. *Vice-Presidents*: Leinster—Dr. Hudson, Dublin; Ulster—Dr. C. D. Purdon, Belfast; Munster—Dr. J. R. Harvey, Cork; Connaught—Dr. Sharkey, Ballinasloe. *Council*: Drs. Baggot, Enniskillen; Charles Benson, Dublin; Samuel Browne, Belfast; Burnside, Clondalkin; H. G. Croly, Dublin; Darby, Bray; Drapes, Enniscorthy; G. F. Duffey, Dublin; Faussett, Clontarf; Gray, Armagh; Grimshaw, Dublin; Hayes, Naas; A. H. Jacob, Dublin; D. Jacob, Maryborough; J. Bellew Kelly, Drogheda; Lyster, Kilkenny; Macnamara, Dublin; James Martin, Portlaoise; Mayne, Ballybrack; Molony, Tulla; J. W. Moore, Dublin; Nolan, Gort; Perceval, Stradbally; Pollock, Blackrock; George Porter, Dublin; T. Purcell, Dublin; H. J. Smith, Donaghmore; Speedy, Dublin; Tagert, Monkstown; Usher, Dundrum; A. J. Walsh, Dublin; Whistler, Bray. *Auditors*: Drs. Morrough, Dublin; Nugent Duncan, Ballybrack.

In the evening, the annual dinner of the Association took place in the Albert Hall of the Royal College of Surgeons, Dr. Robert McDonnell, the President, in the chair. On the right of the chair were Dr. Gordon, President of the College of Physicians; Mr. Porter, Surgeon to the Queen, President of the Dublin Branch of the British Medical Association; Dr. Little, Vice-President of the College of Physicians; Mr. T. A. Purcell, Q.C.; Surgeon-General Crawford, A.M.D.; Dr. Kidd; Dr. Rawdon Macnamara. On the left of the chair were Mr. P. C. Smyly, President of the Royal College of Surgeons; Dr. Darby; Dr. Mapother, Vice-President of the College of Surgeons; Dr. Grimshaw; Dr. Duffey, Honorary Secretary of the Dublin Branch of the British Medical Association; Mr. O'Brien Furlong, B.L.; and Mr. Tufnell. About fifty gentlemen sat down to dinner. After the usual loyal toasts had been proposed and warmly drunk, the toast of the "Army and Navy" was given by the President and responded to by Surgeon-General Crawford, the principal medical officer in Ireland. In the course of his speech, he remarked that he hoped, through the advocacy of the College of Surgeons in Ireland, and through the able advocacy of other corporations connected with the medical profession in this country and others, that the medical departments of both services will eventually be put on a basis that would make it popular not only with the medical profession, but with the country at large, as it ought to be. After the health of the Presidents of the College of Physicians and of the College of Surgeons had been drunk, the President proposed, in the most cordial terms, "Prosperity to the British Medical Association", and coupled with the toast the name of Mr. George H. Porter, the President of the Dublin Branch of the British Medical Association. The toast was most warmly received; and, in responding, Mr. Porter alluded to the identity of the objects and interests of the two Associations, and the harmonious mode in which they had acted heretofore, and would, he was confident, continue in future to act together for the general good. Indeed, the hearty good feeling existing towards the British Medical Association was apparent throughout all the proceedings of the day, and was alluded to with satisfaction by more than one speaker at the general meeting.

We congratulate the Association on its very successful meeting, and on the progress it is making in public esteem. The latter fact is well evidenced by the full notices of the meeting in the daily papers, and the favourable leaders in them on the usefulness of the Association not only to the profession, but to the public at large.

#### THE HARVEY TERCENTENARY MEMORIAL FUND.

THE subscriptions now exceed £1650. During the past week, Colonel Charlesworth has contributed £20, through Sir James Paget; the Faculty of Physicians and Surgeons of Glasgow has given £21; and some members of the East York and North Lincoln Branch of the British Medical Association £2 5s. to the Fund. The accounts are to be audited on Tuesday next, before which date the Honorary Secretaries request that all promised subscriptions may be paid. A meeting of the London subscribers will, by the kind permission of the President of the Royal College of Physicians, be held on Wednesday next, the 12th instant, at 5 P.M., at the College, Pall Mall East, when it will be proposed that the Executive Committee be instructed to make arrangements for the selection of the artist to whom the execution of the

statue may be entrusted. Further subscriptions are still required, and will be thankfully received by Sir George Burrows, Bart., or Mr. Prescott Hewett, the honorary treasurers; by Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone, the honorary secretaries; or they may be paid in to the account of the Fund at the Western Branch of the Bank of England, Burlington Gardens, London, W.

## HOSPITAL AND DISPENSARY MANAGEMENT.

### LIVERPOOL ROYAL INFIRMARY.

WE often hear that hospitals are in debt, and that the treasurers are at their wits' end to devise "ways and means". But it is seldom that an old established charity presents such serious deficiencies as those which are set forth in the recent Report of the Liverpool Royal Infirmary, Lunatic Asylum, and Lock Hospital. During the year 1877 the debt upon these conjoined institutions increased from £422 to £5,131. This appears to have been caused by the legacies falling short of their usual amount, and by a great decrease in the annual subscriptions, while the expenditure was £628 in excess of that of the previous year. Legacies are, no doubt, liable to fluctuation, and this the committee cannot control. But it is otherwise with the annual subscriptions. Surely there must be a fault somewhere. Well may the committee conclude their brief report by saying that the condition of their finances causes them great anxiety, and that immediate steps must be taken to clear off the debt, and to bring the income and expenditure more nearly into harmony.

### ST. GEORGE'S HOSPITAL.

THE following passages in the Annual Report of St. George's Hospital for 1877 show that the Board of Management have given serious consideration to the condition of their out-patients. We could wish that equal attention were bestowed upon the subject at all the other large hospitals.

"The out-patients have increased much of late years—in 1827 the number was 3,139; in 1877, 16,818—and it may be expedient that the governors should again take this subject into consideration. It has occupied their attention for some years, and no doubt the precautions they have taken to restrict the admission of patients as much as possible to those who fairly belong to the class for which the hospital was instituted has been attended with this result, viz., that a smaller number of out-patients are received at St. George's than perhaps at any other hospital.

"When a charity in any way tends to lower the power of self-reliance and self-dependence, it may cease to do good, if it does not do positive harm. If in relieving so large a number of out-patients any number of persons are tempted not to depend on their own earnings for their own support, and to make no provision for attendance in ordinary illness, it becomes a question if such an amount of relief should be given.

"If the locality of St. George's Hospital is considered, it will be found to be singularly surrounded by the homes of the rich, and not the poor. A radius of a mile from the hospital contains Hyde, St. James's, and the Green Parks, Buckingham and St. James's Palaces, and Marlborough House, Grosvenor, Berkeley, Hanover, Portman, St. James's, and all the Belgravian Squares; on the immediate edge is Westminster Hospital, and on the skirts of the radius are St. Mary's, Middlesex, Charing Cross, and St. Thomas's Hospitals, as well as the Hospital for Consumption; so that the portion for which St. George's should supply assistance would be a part of St. George's, Hanover Square, Chelsea, and Brompton. Whether upwards of 16,000 persons are beyond the number that this district should supply as *bond fide* patients, where there are about six Provident Dispensaries, and ample provision has been made by the proper authorities for the *pauper* class, is a question that may require consideration."

### TYRONE COUNTY INFIRMARY.

THE annual report of the Tyrone County Infirmary shows that a large amount of good work has been done during the year. As proposals are now under consideration, which will, if they are adopted, seriously affect the position of county hospitals in Ireland, we are glad to notice the valuable services which this one is rendering to its neighbourhood. Between January 5th, 1877, and January 5th, 1878, seven hundred and eighteen patients were received into the Infirmary; while fifty applicants were refused on the ground that they were either incurable or suitable for the workhouse. Sixty operations were performed, and many severe cases were under treatment. The mortality on the total

number of cases was only eighteen, or 28.4 per 1,000. The average cost of each patient was £2 3s. 3½d., and the cost per bed £39 18s. The total number of beds is fifty; twenty-five of which are for surgical, twenty for medical, and five for ophthalmic cases. The average number of beds occupied during the whole year was thirty-nine. The report, which is drawn up by Dr. E. C. Thompson, is a carefully compiled record of useful work.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 28TH, 1878.

CHARLES WEST, M.D., President, in the Chair.

#### NOTES ON THE SPIRILLUM FEVER OF BOMBAY, 1877.

BY H. VANDYKE CARTER, M.D. (BOMBAY.)

THE author began by expressing his conviction that, by means of the clinical thermometer and microscope, it had been demonstrated that the new Bombay fever was identical with the famine fever, relapsing fever, or recurrent typhus of Europe; and he insisted upon the importance of this fact. Proofs were arranged as being derived from the natural history of the epidemic, from the symptoms noted, and from the pathology indicated, as follows: 1. The rather abrupt appearance of a malady evidently connected with unusual and excessive want, fatigue, and overcrowding; its spread with the increase and subsidence with abatement of these hygienic defects; 2. The remarkable resemblance in clinical characters of this new malady with the relapsing fever of Europe—a resemblance so close as of itself to be decisive of actual identity; 3. As a special feature, the invariable presence in the blood during pyrexia of a minute parasite which, so far as known, was peculiar to one form of fever only, viz., the relapsing. It was also noted as significant that the new fever had raged most at that season of the year when there was least malaria, and had declined when remittents commonly begin to appear. Quinine did not check its course. It was already apparent (in the author's estimation) that this epidemic arose contemporaneously with excessive afflux of famine-stricken people; that, as the pressure of immigration augmented, the "fever" death-rate rose; and lastly that, contemporaneously with diminished influx and with active deportation of families to relief-centres in the interior, this comparative fever-mortality began to decline, though, had it been due to malarious influence alone, the reverse would have been the case. And, with regard to the influence of defective sanitation, there was no evidence that Bombay was in a worse state than previously; besides, relapsing fever did not arise from filth. Most stress was, however, laid upon the proved identity of symptoms and pathology; and, in proceeding to discuss these, reasons were given for introducing the designation "spirillum fever"; and occasion was taken by the author to acknowledge the valuable co-operation of Drs. Succaram, Arjoon, and Anna Moreshwar of the Jamsetjee Jejeebhoy Hospital, Bombay. Some general observations followed, the sources of information being a camp of refuge, and two large hospitals, of which the author had charge at different times. In all, nine hundred cases of "fever" of all kinds, and taken without selection, had been examined; and of these about three hundred and fifty were demonstrated to be instances of spirillum disease; about the same number of cases (chiefly malarious) did not show the parasite, and the remainder were not microscopically scrutinised; they were the milder, obscurer, and mostly sequalar instances. Upon full consideration, the author concluded that upwards of one half (it might be more) of the sickness in Bombay was due to the famine-fever. From the data now alluded to, it was evident that malarious fevers were to be infallibly distinguished by the absence of the spirillum; but the author admitted he had no previous conception of the variety of form and degree which the parasite fever might assume; it might, indeed, like the malarious, be regarded as an order and genus of specific fevers. As to its analogies with the last-named group, secondary or later paroxysms might closely resemble intermittent or aguish attacks; and, as the blood-parasite might or might not be found in such brief exacerbations, much difficulty might be felt in deciding upon their real character. Here experience in India quite accorded with that in Breslau and Petersburg (for example), and different explanations might be offered. The author alluded to an instance he had met with of ague-like fever being occasionally attended with a spirilloid blood-parasite. The more important question of the relationship of the spirillum fever with remittents was briefly discussed; first paroxysms always, and relapses frequently; a persistent pyrexial state, which might be either continuous or remittent—in Bombay it was, perhaps, as

one as the other—but was invariably marked by the presence of the blood-spirillum, whilst this would be vainly sought for in pure remittent attacks. Sometimes the apyretic or free interval was so filled up with daily change of temperature, that the date of relapse was not evident in the chart; if not due to local complications, there might here be addition of a remittent, or, as the author thought not unlikely, of veritable typhus. By means of the microscope, it would always be possible to demonstrate the occurrence of a relapse, even under these circumstances. Symptomatic fevers as complications were next alluded to; and, lastly, the author expressed his concern that remittent fever continued to be the official name of a malady so distinct in important respects as the spirillum or relapsing fevers. Instances of typhus icterodes and of hæmorrhagic typhus were then mentioned in which the blood-parasite was found, as it had been in Europe; it had not been found, however, in "enteric" fever (with a very doubtful exception), varicella, elephantoid fever (where the filaria was detected), and every other ordinary febrile ailment concurring with the specific. Some general remarks on fever followed—the course of future inquiry was suggested. The value of a thorough acquaintance with all stages of the spirillum fever was insisted upon, because only by this means could obscure or late instances be understood. The entire correspondence in symptoms of an ordinary attack of the relapsing fever of Bombay with that of Europe was pointed out, the author adverting to his own illness in part proof, and due prominence was given to this important identification. Instances in which no relapse occurred were particularly mentioned; they were 25 per cent. of all recovered cases; but, if fatal ones were added, of persons dying during or just after a first paroxysm, then the proportion of instances showing but one febrile exacerbation rose to 40 per cent. Upwards of one-half of all recovered cases showed one relapse; 6 per cent. two relapses; 5 per cent. three; and 2 per cent. four relapses. The mean duration of the first attacks and intervals was seven or eight days, with a rather wide range; relapses lasted a shorter time. No difference was noted between an abortive and a relapsing attack, or any fixed relation between the severity of first and second paroxysms. Repeated attacks of the spirillum fever in the same individual at long intervals were well-known in Bombay. Individual symptoms were next reviewed. Prodromata might be wanting, although the spirillum was found within an hour of the initiatory chills of a first attack; they were commonly absent before relapses. Jaundice, delirium, and the typhoid state, and protracted convalescence were more frequent than usual in Europe. Abortion occurred in pregnant women, and was early recognised. Hunger as a symptom was sometimes seen. The mortality, as based upon hospital statistics, might be estimated as 10 per cent.; it was greatest at the height of the epidemic; but latterly several deaths occurred in cases offering typhus symptoms, which had caused a somewhat increased death-rate. The author estimated the rate in ordinary fevers (mostly malarious) as double the above, and in remittents as treble. During the same period, three-fourths of deaths from spirillum fever took place near the close of the first paroxysm, and during the early part of the following apyretic interval. Excepting that of the blood, no anatomical lesion was absolutely peculiar to the fever, and none was invariable. The commonest changes were enlargement of the spleen (nineteen times in thirty-seven necropsies), also fibrinous infarcts (eight) and softening (three); enlargements of the liver (seventeen times in thirty-seven necropsies); fatty degeneration (sometimes acute) of the gland-cells of the liver, kidneys, and spleen was noticed, but not of the heart-muscle; also hæmorrhages in the arachnoid and other serous membranes, and in the intestinal mucous membrane. The influence of age, sex, season, and occupation were noticed; the remarkable limitation of the epidemic to the indigent and those nearest them was pointed out, the middle and upper classes having virtually escaped. The origin *de novo* of this fever from want might seemingly occur, yet this could not be the usual mode of origin, and contagion as a means of spreading the disease must be admitted. Rabbits and pigeons resisted inoculation of infected human blood. Adverting to the sanitary and hygienic condition of Bombay in 1877, Dr. Carter turned to the year 1864, when, from a wholly different cause, viz., excessive prosperity, the town became dangerously overcrowded, and an epidemic of fever broke out which was clearly contagious, and by good authority was compared with typhus. Whether at that time relapsing fever also occurred was now unknown; but the author was inclined to believe that the latter was not a new disease in the Presidency. The remaining portion of the paper was occupied with a description of the spirillum (spirochæte) and other blood-elements detected in this disease during the many hundred observations which had been made in Bombay. The author had had the satisfaction of finding that his independent experience entirely corresponded with most of that collected during recent years in Europe; and he regarded this identification of the spirillum fever as a substantial addition to our previous knowledge.

SEQUEL TO A CASE OF ANEURISM OF THE AORTA, AND THE  
INNOMINATE, SUBCLAVIAN, AND CAROTID ARTERIES,  
TREATED BY THE DOUBLE DISTAL LIGATURE.  
BY RICHARD BARWELL, F.R.C.S.

Robert Watson was exhibited to the Society on November 13th, when the paper entitled as above was read. On November 14th, he left the hospital. On the 20th, he came to the hospital on formal business; and, as he was suffering from bronchitis, Mr. Barwell persuaded him to remain. He was very intractable, and, not being allowed brandy, left on the 22nd. He walked home (about two miles) very thinly clad, through snow and sleet, sat four hours in wet clothes without a fire, became rapidly worse, and died on November 24th. On November 25th, a *post mortem* examination was made. The aneurism, which appeared solid, was removed, together with the heart and great vessels. No other disease was discoverable, except very acute bronchitis (muco-pus in the large and small bronchi), hypostatic pneumonia, and oedema of the lungs. The blood in the arterial system was dark, like that of the veins. The aneurismal tumour, rather larger than a tennis-ball, sprang from the junction of the first and second parts of the aorta. Its pressure had altered the course and relations of the trachea and oesophagus; the large veins also were peculiar. It was remarkably hard and firm. At its upper part, it was elongated into a subsidiary enlargement, which lay in the neck, and was in front divided from the rest of the aneurism by a groove marked in it by the clavicle. The back of the sac was moulded on the apex of the lung. The sac was laid open from behind forward. There was within it, still persistent, a globular cavity, perhaps an inch in diameter; this was surrounded by very firm clot of variable thickness; and in front, close to its opening into the aorta, it was rather more than one-third of an inch thick; behind, an inch and a half. The subsidiary tumour was quite obliterated, so that here the clot was more than two inches thick. No vessel opened out of the aneurism; the innominate being, like the right subclavian and carotid, obliterated. The left vessels came off from the aorta itself below the mouth of the aneurism. The specimen showed that the tumour had greatly shrunk since the operation; that the whole tumour was as much filled as could be expected in the time; that, had the man chosen to remain in the hospital, or been moderately prudent, the whole cavity must almost of necessity have become obliterated, since the aneurism, thickened by hard clot, could neither have enlarged nor burst; and, since there was no thoroughfare within the sac, there could have been no blood-stream through it. In fact, though the man, by his own perversity, contracted an intercurrent fatal disease, the aneurism was to all intents and purposes cured.

TWO CASES OF INTUSSUSCEPTION, IN ONE OF WHICH ABDOMINAL  
SECTION WAS PERFORMED. BY C. HANDFIELD JONES, M.D.,  
F.R.S., AND HERBERT W. PAGE, M.C., F.R.C.S.

Two cases were recorded, in patients of Dr. Handfield Jones, in St. Mary's Hospital. The first, a harness-maker aged 60, admitted May 12th, 1874, had, although enjoying good health, passed blood *per rectum* for the previous twelve months. On May 5th, he was seized with abdominal pain, and then passed a teaspoonful of clotted blood. The pain became constant after May 8th, and, when admitted, a tumour was found in the cavity of the bowel, round which the finger could be passed, and there was dulness in the left flank, with constipation. He was examined on the 21st, with a view to operation; but the surgeon (since dead) concluded there was cancerous disease, having brought away a portion of growth on the finger. The man died on the 23rd. Extensive peritonitis was found *post mortem*, and a large invagination projecting into the rectum, which could be reduced with ease, and there was no cancer. Regret was expressed at the delay and mistake in diagnosis, as operation might have easily relieved the condition, and perhaps have saved life. The second case presented features of great interest. A boy aged 5 was admitted December 31st, 1877, with a history of having lost flesh and been very ill for six weeks. He had severe paroxysms of pain in his abdomen, varying much in frequency, and with some diarrhoea. He improved during the first few days; but, on January 14th, he had more pain, and there was dulness on percussion in the left flank. This condition increased, and on the 20th, the child being very ill, and there being a distinct hard lump in the left iliac fossa, inflation was performed *per anum*, and was followed by a rapid subsidence of all the urgent symptoms. His state continued very variable from day to day until February 4th, when the tumour again appeared, and was a second time relieved by inflation. On February 11th, for a third time, and again on February 16th, the tumour reappeared, and was removed by insufflation; and on February 25th, the operation was again repeated for the fifth time, and caused the disappearance of the tumour, then much larger than before, and both seen and felt in the left iliac fossa. He was taken out of the hospital by his

parents on February 27th, with a warning that a recurrence of the disorder was almost certain. He was readmitted on March 4th, in an alarming state, the symptoms having returned two days before. A large tumour was now felt, reaching from the iliac to the umbilical region; and inflation, when performed in the afternoon, only changed its position, but did not make it disappear. The child continued in great pain, and in the evening insufflation was again tried, and failing, water was injected, but without success. On the following day, he was much worse; and at 5 P.M., when pulseless and collapsed, he was seen by Mr. Page, who at once performed abdominal section. The tumour was so large that it was necessary to prolong the incision above the umbilicus, and to remove the small intestines from the abdominal cavity. Traction on the upper end of the volvulus was only successful in the extrication of about two inches of ileum; and an attempt to draw off the ensheathing part at the lower end was frustrated by the presence, then discovered, of a second and lower intussusception of the colon, in which the order of parts was reversed—the inferior portion being ensheathed in the upper, which thus became the ensheathing part. The two volvuli met and overlapped each other at their extremities, and it became necessary to reduce the backward intussusception before the ordinary invagination could be relieved. Owing to the great distension of the bowel and slight adhesions at the ultimate part of the intussusception, this was a work of much difficulty, and was only accomplished by considerable force. The upper or more usual invagination was then reduced with great ease, by gently squeezing the lower end of the volvulus—an action which simultaneously drew off the ensheathing, and pushed out the ensheathed, part of the bowel, the vermiform appendix being the last to appear. There was some visible congestion and thickening about the cæcum, but no general peritonitis or adhesions. The operation, of which a detailed account was given, lasted an hour and a quarter. The child considerably rallied after it, but died exhausted the following morning, having lived nine hours and three-quarters. At the necropsy, the lips of the wound were found adherent. There was commencing peritonitis of the small intestines, but none of the large bowel. At a point corresponding with the upper limit of the volvulus, the mucous membrane of the ileum was swollen and greatly congested, and that near the vermiform appendix was much the same. The meso cæcum was so lax as to allow the cæcum to be drawn over the left iliac fossa. The method of reducing the upper volvulus was specially referred to, as confirmatory of Mr. Hutchinson's experience, recorded in the fifty-ninth volume of the *Transactions*, that pulling down the ensheathing part rather than pulling out the ensheathed part was the true mode to pursue. Reduction of the backward intussusception was rendered most difficult from the slight adhesions at its furthest end, and from great distension of the gut; and, although accomplished without damage to the structure of the bowel, it was thought that such force as was requisite might itself have been dangerous. Reference was made to the long continuance of pain before any definite appearance of tumour; and it was suggested, as an explanation of the occurrence of intussusception, that pain and the subsequent motor derangement must be ascribed to a functional disorder of the abdominal nerves and ganglia, a relaxed state of a lower segment certainly favouring the intrusion of an actively contracting part above. It was, therefore, most probable that the essential condition of intussusception was a local paralysis of a portion of the small intestine, which became the sheath of the volvulus. Neuralgic pain in other parts was associated with motor paralysis, and probably was so in the abdominal organs. At the same time, the laxity of the meso-cæcum might throw light on a predisposing cause of the intussusception. The second and ascending intussusception formed a very remarkable feature in the case, the existence of a single instance of such a condition having been called in question by the late Dr. Brinton. The absence of peritonitis and adhesions after many recurrences, and the presence of slight adhesions only when the child had been taken home, and when there was long delay in resorting to inflation, showed how necessary it was that this treatment should be had recourse to as soon as intussusception was evident; while the state of the mucous membrane, although the serous surface of the bowel might be free from inflammation, pointed out the imperative need of surgical interference at the earliest possible moment after other means had failed to give relief.—Mr. GAY remembered a case of his own which was somewhat similar. He was called in consultation to see a lady, more than seventy years old, supposed to have suffered for several years from internal piles. Sometimes there was bleeding and difficulty of defecation; and when this last was overcome, blood was passed in some quantity. He could find a considerable swelling in the rectum, which seemed to be a polypus when examined by the speculum, and to that he applied a ligature. When he next saw her, there were peritonitis and vomiting, and no motion had been passed. He removed the ligature, and separated the part by the knife. She improved for a time, but after a few weeks she

sank and died. No *post mortem* examination was allowed; but the tumour, when examined, was found to be an old invagination, and it could even be unsheathed with a little trouble. The case showed, at all events, that invagination might last for years without giving rise to marked signs.—Mr. BROOKE thought a small bougie passed round about the tumour might be of use in detecting such cases.

FATAL PURPURA, FOLLOWING THE ADMINISTRATION OF A SINGLE DOSE OF IODIDE OF POTASSIUM, IN AN INFANT THE SUBJECT OF CONGENITAL SYPHILIS; WITH REMARKS UPON SYPHILITIC AND IODIC PURPURA. BY STEPHEN MACKENZIE, M.D.

An infant aged five months, the subject of well-marked congenital syphilis, had prescribed for it a mixture containing iodide of potassium, in two-and-a-half-grain doses. About three-quarters of an hour after taking the first and only dose, the child's face was noticed to "turn black"; and this rapidly increasing, it was brought to the London Hospital, three hours after taking the medicine. When first seen, the whole of the face was swollen, of a purplish-black tint, the eyelids closed from extravasated blood, the lips and chin tensely swollen and of an almost black colour. The cheeks were discoloured by aggregated patches of purpura. There were a few spots on each arm, but at this time none elsewhere. There were also scattered over the body a few abortive pustules. While the patient was watched, the purpuric patches perceptibly increased in size until, in the course of an hour or so, the scalp and face were fairly covered. The next day, the whole face was swollen and of a port-wine colour, and there were purpuric spots on the arms and legs. The extravasated blood underwent some changes of colour, and parts of the skin of the face became necrosed in the course of this and the following day. The child died sixty-eight hours after taking the medicine. The necropsy showed characteristic signs of syphilis and ulceration of the intestines. The previous medicines which the child had been taking were procured and analysed; they were free from iodine. From the quantity abstracted from the bottle containing the iodide of potassium, it was certain that not more than two-and-a-half grains had been given to the patient. The author stated that, as purpura was known to occur in connection both with syphilis and the ingestion of iodide of potassium, it was necessary to review what was known concerning syphilitic and iodic purpura. He especially referred to cases of the former recorded by Wilson Fox, Bälz, and Behrend, and others observed by himself. As regarded iodic purpura, he alluded to the writings of Fournier, Van Buren, Bradbury, and Sydney Ringer, and to cures he had himself seen. His conclusion was that, in his case, the fatal purpura was due to the iodide of potassium, though the syphilitic dyscrasia under which the patient was labouring might have contributed to the result.

## PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 7TH, 1878.

CHARLES MURCHISON, M.D., LL.D., F.R.S., President, in the Chair.

*Cancer of the Tonsil.*—Mr. BUTLIN read a report, signed by himself and Dr. Goodhart, upon two cases exhibited by Mr. L. Browne at a previous meeting. In one case, there was a large soft growth—a lympho-sarcoma—implicating the right tonsil, the posterior wall of the pharynx, and the soft palate, which had a ragged sloughy surface; in the second case, the left tonsil was defaced by a ragged ulcer, which had extended from the base of the tongue, and which was an epithelioma.

*Ulceration of the Bowel in connection with Granular Kidney.*—Dr. DICKINSON exhibited these specimens, which he described as rare. In his Croonian lectures two years ago, he had described two other cases, in both of which existed granular kidneys, cardiac hypertrophy, and arterial tension, with ulceration of the ileum, which was nearly, if not quite, penetrated, and both had died with peritonitis. No other cause also for the ulceration had existed in either case, unless it was the granular condition of the kidneys. Since then, a third case exactly similar had been under Dr. Greenhow in the Middlesex Hospital. The present was the fourth case known to him; and the patient, a man aged 20, had been in St. George's Hospital, at first under the care of Mr. B. Carter, suffering from retinitis due to granular kidney. He had hypertrophy of the heart, with astonishing hardness of the pulse; in fact, Dr. Dickinson described it as the hardest pulse he had ever felt in his life. He had hæmorrhages from the bowels and nose, and into the retina; he also had peritonitis, became prostrate and collapsed, and died. The kidneys were found to be granular, and contained much fibroid growth. The renal symptoms had been due to scarlatina con-

tracted fourteen years previously, and accompanied at the time by dropsy. He had also the same state of ileum as was found in the three other cases. The peritoneum contained purulent fluid, and the bowel was pierced in two places. Within the bowel were circular ulcers. The patient had not had typhoid fever nor tuberculosis. He had pigmentation of the affected intestine, which led Dr. Dickinson to suggest that possibly the ulceration was due to interstitial hæmorrhage into the bowel, and was a consequence of the granular state of the kidneys.—The PRESIDENT asked what was the explanation that in all four cases the patients had been exceptionally young for such a condition of the kidneys.—Dr. DICKINSON said that in this fourth case it was due to scarlet fever; in one of the other cases it had been due to calculous disease.—The PRESIDENT inquired what was the temperature in the cases? what was the proof that typhoid fever was not the cause of the ulcerations in the bowel?—Dr. DICKINSON replied that there was no history of typhoid, and no rise of temperature in either case to cause any suspicion of typhoid. The cases were chronic; and in the last case the temperature was certainly not high.

*Renal Calculus composed of Mixed Carbonate and Phosphate of Lime.*

—Dr. ORD exhibited this specimen, taken from a left kidney that had been destroyed by a sarcoma which had occluded the ureter. The kidney was merely a lobulated cyst, and contained purulent fluid and a calculus of the usual elongated and branched form of calculi found in the pelvis of the kidney. Such calculi were formed from three or four nuclei corresponding to the pelvis and infundibula, and there growing coalesced into one large calculus. This specimen had originally four nuclei, consisting of uric acid and urate of ammonia. The central portions of the branches were friable, and composed of phosphate of lime, interspersed with needles and prisms of urate of soda or lime, coated with a mixture of urate of ammonia, and sometimes with phosphate or carbonate of lime. The calculus with its different layers showed well the varying stages of its growth. Its friability proved that it had almost certainly been formed after partial occlusion of the ureter had produced dilatation in the pelvis of the kidney, allowing sediments to lie in diverticular sacs out of the track of the current of urine. Where carbonates entered into the composition of calculi, such calculi were probably formed out of the course of the urine where other fluids than urine would be present. This calculus did not yield any trace of indigo or of indigogenous material, although it came from the body of the patient in whose right kidney was found the indigo calculus exhibited recently by Dr. Ord at the same Society.

*Two Specimens showing the Spontaneous Disintegration of Calculi in the Bladder.*—Dr. ORD also exhibited some calculi sent to him by Mr.

Lockhart of Blackheath, twelve of which had been passed by a gentleman aged 56, since dead of bronchitis. All were segments of a fusiform calculi, and looked like the fragments of an exploded shell. Some had a fawn-coloured basis of uric acid; some were pale, and covered with urate of ammonia. They had no nuclei, but in each calculus the pyramidal end was hollowed out where the nucleus had originally been. The second set of thirty-two calculi had been sent to Dr. Ord by Mr. Buckston Browne. Some of these were water-worn and polished; some had perfectly sharp and untouched edges. They had been passed at various times by the patient, a male aged 63, who had died of uræmia. The basic substance was almost pure uric acid arranged in radiating fibres, the fibres being interrupted by laminae. All were fragments of fusiform calculi which appeared to have undergone spontaneous disruption in the bladder, and then become coated with urate of ammonia. The calculi were evidently originally deposited from an acid urine; the urine had then become more alkaline, and the outer layers of the calculi were consequently of less acid material. In this changed state of the urine, the nuclei had swollen and acted as a bursting charge in a shell.—The PRESIDENT inquired if in such cases the nuclei were never found.—Dr. ORD replied that he had searched for them in vain. In the College of Surgeons' Museum, however, was a specimen exhibited as a disrupted fusiform calculus, in which the apex was not truncated but perfect, and composed of a nucleus.

*The Microscopical Characters found in Tissues affected by Measles.*—Dr. BRAIDWOOD of Birkenhead exhibited specimens of drawings, prepared by himself and Mr. Vacher. They were in continuation of their previous researches on contagium; but, as specimens of scarlatinal disease had not been obtainable, they had worked at measles during an epidemic of that disease in Birkenhead. He commenced by remarking that the observations on small-pox, presented last year to the Society, had been completely confirmed by their later microscopical studies of that disease. Human tissues had no counterpart amongst the lower animals. The breath of a morbillous patient, on the third day of the illness, being examined microscopically, was found to contain numerous spherical sparkling bodies, and others elongated with sharp cut ends,

sparkling and colourless. These specimens were contained in the glycerine into which the patient had breathed. Two fatal cases had been examined; one child had died on the eighth day, the other about the fifteenth, after the appearance of the rash. The body in each case was examined within twenty-four hours of death. The specimens, when hardened in alcohol, had been cut in sections and prepared by Cole and Son. In the first case, the skin showed thickenings of various parts, due to great proliferation of the cells of the rete Malpighii, extending along the hairs and the sweat-ducts into their glands. In the true skin were sparkling spherical and spindle-shaped bodies, which did not take the carmine tinge, which resembled the so-called micrococci of vaccine, but were larger, were not found in the sweat-glands, ducts, or hair-follicles, nor more deeply situate than the level of the sweat-glands. The lungs showed infiltration of the air-vesicles, and of the inner surface of the bronchial tubes, by altered blood-corpuscles and excessive proliferation of cells; amongst which were found also the sparkling spherical and elongated bodies such as were found in the skin. The same bodies were discovered in the liver, scattered around the bile-ducts. In the kidneys, spleen, and mesenteric glands, nothing distinctive was found. In the second case, the swelling of the skin was less pronounced; but similar contagium-particles were found. In the lungs was pneumonic infiltration, with bronchial catarrh and the specific organisms found in the first case. The same spherical and elongated contagium-particles were found in the liver, especially in the tissue immediately outside the walls of the vascular spaces. Nothing especially distinctive was found in the spleen or kidneys; the former was large and friable. These observations pointed to the existence of a "measles-micrococcus", to be ranked with vaccine-micrococcus, and probably with a scarlatinal species; it was probably developed chiefly in the lungs, and, passing into the respired air, formed an important means of spreading the disease.—The PRESIDENT considered that the Society was much indebted to Dr. Braidwood for having come so far to read his paper. The specimens were beautifully prepared, and the drawings accurately represented them; but the real point was: were the particles which had been described the real contagium-particles of measles? That observation of the particles found in the breath, if it should be confirmed by further observations, was most important. He would say, multiply the observations, in order to discover if such particles were always found in the breath in measles. Could they be cultivated also? If so, and the crop were found to be capable of reproducing measles, the experiment would go a long way to prove that they were the true contagium-particles of the disease.—Mr. MORRANT BAKER inquired if Dr. Braidwood had examined the breath in the same manner in the other exanthemata.—Dr. THIN believed some such observations had been recently made. Prickly heat, measles, etc., so far as their skin-affections were concerned, all depended upon congestion of the skin, and yet, to the naked eye, were all different from one another. He commented on the characters of bacteria, and thought it impossible to say, from microscopic observation, whether the particles described by Dr. Braidwood were living organisms.—Mr. BURLIN thought it extremely probable that bacteria would usually be found in the breath in measles, as they were contained in large quantities in the fur of the tongue. Had Dr. Braidwood examined the respired air in the diseases?—Dr. LEARD described Tyndall's apparatus for observing how certain odours absorbed heat-rays, and thought that advantage might result from the examination of odorous emanations from the bodies of those afflicted with contagious diseases.—Dr. WILBERFORCE SMITH had often examined the fur on the tongue, and found it to consist of a fungus-material mixed with epithelia. Had Dr. Braidwood examined the bladder in these cases? He himself had often noticed desquamation of the bladder epithelium in measles.—Dr. ORD remarked that one case had been examined late in the disease, on the fourteenth day in fact, when the rash had passed away, whilst the other case had been examined at a different date. Was there any difference in the condition of the bacteria in the two cases, and what was the size of the particles?—Dr. COTLAND inquired how the specimens had been prepared for examination. The reagents which might be used varied the appearances so very much, that even Dr. Klein had been deceived thereby. He thought conclusions should be withheld until the observations had been multiplied under various conditions.—Dr. BRAIDWOOD, in reply, regretted that his observations had been so few, but had thought it best that they should be brought before the Society as soon as possible. He was glad of the discussion which had arisen. The research was difficult, because he and Mr. Vacher could not use artificial light for their observations, and during the day he was otherwise much engaged. Although the particles under the microscope, from differently diseased tissues, might appear the same, and have a similar chemical reaction, yet they would produce quite different effects when introduced into the favourable soil of the human body. They could scarcely be cultivated,

except in the natural way, as was the case with the vaccine micrococci. The activity of vaccine lymph was certainly due to these spherical particles. He had not examined the respired air in cases of other diseases, and was quite willing to admit that the causes of error in single observations were very numerous. The particles in the breath in that one case were like the particles found in the tissues. He should continue these observations upon the breath in other cases. He had not examined the bladder. He had called the particles "elongated sparkling bodies" rather than bacteria. There was a distinct difference in the appearances found in the skins of the two patients who had died at different stages of the disease. The spherical bodies described by him were a trifle larger than the vaccine micrococci, which were the 1-20,000th of an inch in diameter. He and Mr. Vacher had employed the simplest form of examination. All their specimens had been prepared alike in alcohol, and they had examined each slide over and over again.—Dr. DICKINSON inquired if Dr. Braidwood had had his attention called to the observations of Dr. Salisbury, made many years ago, to the effect that the contagium of measles was connected with the growth of wheat.—Dr. BRAIDWOOD had not met with these observations. He said also that it must be remembered that neither measles nor scarlatina could be cultivated in the human subject.

*Epithelioma of the Female Lip.*—Dr. THIN showed microscopical preparations taken from such a case under the care of Mr. Bell of Edinburgh. The patient was a widow aged 65, who had smoked for twenty-eight years, and who in the spring of 1877 blistered her lip by using a new clay-pipe. She returned to her old short "cuttie" for two months; but, as the lip pained her, she then discontinued smoking. When she came to Edinburgh last January, there was at the right angle of the mouth an ulcer with a hard dry base, extending on the cheek about an inch and a half. The tumour was excised, and the patient cured. The usual characteristics of epithelioma were revealed by the microscope, the mucous glands being especially distended and dilated; whilst in the surrounding skin the sebaceous glands were infiltrated, whilst the rete mucosum was not affected.

*Cancerous Ulcer of the Skin of Forty-three Years' Duration.*—Dr. THIN also exhibited this specimen, which had been removed by Sir James Paget on January 21st from a female aged 68, who, about forty-three years ago (when she was consequently twenty-five years old), had first noticed a pimple over the spine of the left scapula, which five years afterwards was of the size of a pea, was pronounced to be a common wart, and was removed by ligature. It returned, and in ten years had become as large as a moderate strawberry, was pronounced to be a "vascular wart", and was again removed by ligature. After this operation, the base had never healed, but remained as a superficial ulcer, which had since spread slowly during twenty-seven years, causing little pain, but discharging pus freely. During the last year, however, the pain had much increased, and the ulcer had grown rapidly, and, as her health was failing, Sir James Paget had thoroughly excised it. At the time of operation, although it covered the whole of the scapula, it was entirely removed, only healthy tissue being left. Progress was most satisfactory three weeks after the operation, the wound having a healthy granulating appearance. There had been no concomitant glandular affection. The edge of the ulcer was surrounded by an elevated rim, the product of cell-growth, which spread as columns of close packed cells into the surrounding rete mucosum; but which were more scattered in the deeper layers of the skin. The cells were like the lining of the sweat-glands; and these latter were filled with cell-growth. The case was neither one of epithelioma, nor was it a rodent ulcer, but it resembled Verneuil's adenoma of the sweat-glands. Mr. Gaskoin had recently exhibited a specimen of a similar kind at the Royal Medical and Chirurgical Society.

#### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MAY 1ST, 1878.

JAMES H. AVELING, M.D., Vice-President, in the Chair.

*Effusion of Blood into the Peritoneal Cavity.*—Dr. BARNES exhibited two specimens illustrating two forms or causes of intrapelvic blood-effusions. The first was a tubal gestation which had burst. The gestation was estimated at seven or eight weeks. The sac was within an inch of the left angle of the uterus. The patient had undergone a fatiguing journey, and died under symptoms of shock and collapse. The other specimen was an illustration of a more rare description. A patient was admitted into St. George's Hospital suffering from retroflexion of an enlarged uterus, causing much pelvic distress. The displacement was reduced under anaesthesia without much difficulty, and a Hodge's pessary applied. Though relief followed on the second day, pain set in, and the pessary was expelled while coughing, and three

days after she died rather suddenly. At the necropsy, the abdominal cavity was found full of blood; the source of the hæmorrhage was traced to the pelvis, where an imperfect cavity had been formed by the adhesion of the retroflexed uterus to the omentum and intestine.—Dr. JOHN WILLIAMS, Dr. HAYES, Dr. WILTSHIRE, and Dr. HEYWOOD SMITH made remarks.

*The Uterus during Menstruation.*—Dr. CORY showed some microscopical sections of an uterus taken from a subject who died suddenly the same day as menstruation commenced. These showed well the appearances described by Dr. John Williams. The mucous membrane was separating from below upwards, that part of it nearest to the cervix had already separated, and immediately above this some remains of it could be seen hanging in shreds, which still further towards the fundus it was still intact.

*Fracture of Cranium in a New-born Child.*—Dr. POOLE of Sidcup exhibited the cranium, lungs, and heart of a recently born child. When he was called to the mother, a servant girl, she stated that six hours previously, whilst in bed, labour came on, and the child, in being expelled, fell over the edge upon the bare boards. She was lying upon her right side, with her back close to the edge. The left frontal bone had three fractures, proceeding from the coronal suture; the left parietal had three an inch and a half long, from the sagittal suture; and the right parietal had one long fracture, starting from the same suture. The lungs gave evidence of respiration having been well established. The funis was twenty-four inches long, and was ruptured eighteen inches from the umbilicus. The bed was twenty-six inches from the floor; and the question was, could the fall, broken by the resistance of the funis, have caused the fracture?—Dr. AVELING thought it very doubtful whether this case should be discussed by the Society while still *sub judice*, and he submitted this point to the Fellows.—After remarks from Dr. BRAXTON HICKS, Dr. ROUTH, and Dr. WILTSHIRE, Dr. MURRAY proposed that the discussion should be deferred until the case had been adjudicated.—This resolution was seconded by Dr. BRUNTON, and carried unanimously.

*A Case of Cæsarean Section* was communicated by Dr. BRAXTON HICKS. The patient, when eight months advanced in pregnancy, was admitted into Guy's Hospital on account of malignant disease of the vagina, etc., seriously impeding the passage. The rectum was surrounded by a malignant deposit, and the recto-vaginal septum was consolidated into a dense and unyielding mass, nearly filling up the vagina, and almost preventing the finger from reaching the os. Delivery *per vias naturales* being impracticable, it was decided to perform Cæsarean section about a week before the full term. Feverish prostration and pains of labour occurred, however, three days after admission, and the operation had to be undertaken under these disadvantageous circumstances. The placenta was found to be seated beneath the incision; there was, however, very little bleeding. The uterine wound was brought together by grasping the uterus, and uninterrupted sutures of carbolised silk were passed through the peritoneal coats. The external wound was then closed, and a catheter passed through the os uteri, so as to facilitate the breaking up of clots, and to allow irrigation. Bilious vomiting soon set in, and the patient sank about twenty-four hours after the operation. On *post mortem* examination, the whole of the uterine wound was found gaping, every stitch having been torn away. There was a small quantity of grumous purulent fluid in the pelvic peritoneum. Dr. Hicks considered that the accession of irritative fever previously to the operation had much influence in the fatal termination, and that the very severe vomiting, coupled with a vigorously acting uterus, had doubtless caused the tearing away of the uterine stitches.—Dr. GODSON referred to the successful cases of Cæsarean section lately brought forward by Dr. Edmunds, where no uterine sutures had been employed, and asked Dr. Hicks what circumstances induced him to use sutures in his case, for the result showed how useless they had been.—Dr. HEYWOOD SMITH asked to what depth the sutures had been introduced.—After some remarks from Dr. MURRAY, Dr. BRAXTON HICKS stated, in reply, that he had put in the sutures through the uterine wall to the depth of from a quarter to half an inch; he was led to employ them because the wound gaped to such an extent. He thought it might be said that when a case promised well, sutures were not required, and when the reverse, sutures were of little use.

*Pregnancy complicated with Malignant Growth in the Vagina and Rectum.*—This case, which was contributed by Dr. POTTER, occurred in the Westminster Hospital in January 1876. The patient, aged 29, was five months pregnant; and, on vaginal examination, a hard lobulated mass was found occupying the upper and posterior junction of the canal, and extending to within two inches of the vulva. The cervix and os uteri were not implicated. *Per rectum*, a large fungating mass could be felt, evidently identical with that occupying the vagina. The bowel was almost impervious. When about seven and a half months

pregnant, premature labour was induced by means of a gum elastic catheter. In eight hours, labour had fairly commenced. The presentation was vertex and footling, and delivery was completed by pulling down the feet; the head ultimately being brought through the narrowed space with the forceps. The child was born alive, and the mother made a good recovery from her confinement. Colotomy was subsequently performed, and the patient died seven days after from peritonitis. No necropsy was permitted.

*Membranous Dysmenorrhœa.*—A case was reported by Dr. CORY as supporting Dr. Hausmann's view, that membranous dysmenorrhœa is due to an imperfect imregnation. The patient, previously to her marriage at the age of 30, had never passed any membrane. She aborted three times between the second and third months during the first two years of married life. Since then, she had almost invariably passed at her menstrual periods membranes, which proved to be very perfect casts of the uterine cavity, and presented all the naked-eye and microscopical appearances of its mucous lining. The membrane usually came away on the second day of menstruation, previously to which the dysmenorrhœa was acute. Later on, she had lived apart from her husband nine months, during which time she had menstruated regularly without passing any membrane.—Dr. GODSON showed, as bearing upon this case, a specimen of a decidua membrane, with a very small vomer upon it; and he remarked that, had it not been very carefully examined, the vomer would probably have escaped notice, and the membrane have been looked upon as dysmenorrhœal.—Dr. GALABIN said that the facts of Dr. Cory's case appeared to establish the interpretation adopted by the author, that the membrane thrown off in successive months was the pro-duct of conception repeatedly occurring. On this assumption, it afforded interesting evidence as to the rate in the menstrual cycle at which conception may occur. Since the period was never delayed more than two or three days over time, conception must have occurred shortly after the preceding period on each occasion, since otherwise there would have been no time for the decidua to develop.—Dr. JOHN WILLIAMS thought there could be no doubt that the membrane exhibited by Dr. Cory was the decidua containing an im-pregnated vomer. The fact that the membrane was only passed when the woman was living with her husband favoured the view that it must be a kind of abortion, and for this reason he objected to the case being quoted as one of membranous dysmenorrhœa. Such a name ought not to be given in any case in which the lining membrane of the uterus was not expelled.—Dr. AVELING said that he had some hesitation in accepting the view put forward in the paper. He thought that a hyperæmic condition leading to membranous dysmenorrhœa might have been caused by the irritation of sexual intercourse.—Dr. POTTER and Dr. JOHN BRUNTON also made some remarks.

*Treatment of Chronic Inversion of the Uterus.*—Mr. LAWSON TAIT contributed a note on this subject. After alluding to the proposals of Simpson and Tyler Smith to rectify the displacement by continued pressure, and mentioning the disadvantages of the operation recommended by the latter, Mr. Tait referred to the instrument devised by Dr. White of Buffalo. It was apparent to him that no plan could so efficiently diminish the size of the inverted uterus as pressure upon it by a conical cup; and it was equally evident that the best way of dilating the contracted and inverted cervix was to make it do the work, as it were, by pressing upon itself. He, therefore, abandoning the pelvic curve of the older instruments as useless, had box-wood cups made of three different sizes, each with a straight stem about six inches long, with notches at the end for strings. The case to which the treatment was applied was that of a young woman aged 20, who had been delivered by a midwife ten weeks previously. The uterus was completely inverted, and thorough involution had taken place, so that the inversion had passed into the chronic stage. After she had been in the hospital for six weeks, the large rigid cup was introduced under ether, and a double thread of elastic was applied to the stem, and fastened to the waist in such a way as to give a strain, probably not exceeding a pound at the utmost. The next morning the uterus was found reinverted, and enclosing the cup. On the removal of the latter, it was found that the reinversion was not complete; and the smallest sized cup was then introduced with the effect of securing perfect reduction. The simplicity of the treatment in this case, he thought, entitled him to say that in future very few cases should be submitted to the extreme measure of amputation.—Dr. AVELING remarked that the case would serve to encourage us in the treatment of a very difficult condition, which, till recently, had been thought only relievable by amputation. The use of straight stems was, however, not a novelty; they had been first advocated by Madame Boivin, and Dr. Braxton Hicks had employed an instrument very similar to a stethoscope.—Dr. GODSON said that the three cases recorded in the last volume of the Obstetrical Society's *Transactions* of amputation of the uterus for inversion, which had been

a subject of surprise to Mr. Lawson Tait, were taken from a large number of cases of inversion which had been treated in St. Bartholomew's Hospital, and were brought forward not for the purpose of recommending the operation, but to show that the uterus might be amputated without any great danger to the patient's life. He thought there were two different kinds of cases of inversion of the uterus. Some might be easily reduced by pressure, and he had seen one which reinverted itself the day after pressure had been applied by the hand alone. That treated by Mr. Tait appeared to belong to this category. Others seemed to defy all attempts at restoration. In such cases, if the life of the patient were in jeopardy from the profuse and uncontrollable hæmorrhage, which was an alarming symptom in the cases recorded by Dr. Gibson, amputation was not only justifiable, but was demanded to save life. If bleeding to a dangerous extent were not present, it was, on the other hand, the duty of the practitioner to continue his efforts to restore the displacement.—Dr. J. BRAITHWAITE of Leeds had recently had a case of inversion which had been treated by means of continuous elastic pressure. In order to apply this, no special apparatus had been procured; an ordinary boxwood stem and cup pessary had answered the purpose admirably. The cup was covered by a soft India-rubber circular pessary containing air, made to adhere to the cup by means of shellac. The proximal end of the stem was set in an India rubber band, and this was fastened to an abdominal belt. In the case named, after the pressure had been well sustained for four days, the inversion was forced back returned, and no difficulty was then found in completing the reduction.—Dr. HAYES thought that, in recording cases of inversion of the uterus, the degree of involution which had taken place should be mentioned. The difficulty of reduction was directly dependent upon this, and only indirectly upon the duration of the displacement.

#### EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, MAY 8TH, 1878.

JOHN MURRAY, M.D., President, in the Chair.

*The Origin of Infection.*—Dr. THORNE THORNE read a paper on the origin of infection. At the outset, he explained that the question he proposed specially to hold in view was whether any case of acute specific fever could arise independently of an antecedent case; and, with a view to the elucidation of this question, he gave a review of the principal grounds leading some observers to answer the question in the negative, others in the affirmative. The various arguments which might be brought forward on both sides of the question were illustrated by typical instances from the author's own experience and from that of other observers. Those in favour of the view that the infectious fevers are exclusively self-propagating were as follows. First, there was the general inference to be drawn from the well known fact that these diseases largely owed their spread to communication with prior cases; and, this being the ordinary source of infection, it might be urged that it was the invariable one. Then it was suggested that this argument was strengthened by consideration of the frequent discovery of new channels by which the poisons of the specific fevers might be conveyed, as by intermittent water-services, etc. Cases were next cited which, having been brought forward as favouring the *de novo* origin theory, were, as the result of the subsequent discovery of some apparently trivial circumstance, found in reality to favour exactly the opposite view. The extreme variation in the length of periods of incubation of the various specific fevers was next illustrated by numerous examples, and named as constituting a source of error not sufficiently recognised. The prolonged period during which some of the poisons of these diseases remain a dormant condition was also pointed out, and illustrated by typical cases. And, finally, the long continued immunity from these fevers which certain countries had enjoyed prior to the diseases being imported and then by contagion, was described. The arguments on the opposite side were next considered; it being, however, admitted beforehand that, since those who believed in the independent origin of the specific poisons had to prove a negative, their task was more difficult than that of their opponents. Judging from analogy, however, they were supported by the possibility of the spontaneous generation of the traumatic infections, and by the artificial production of cases of apparently specific malignant peritonitis by inoculations from selected cases of simple peritonitis. Then there was the unexplained occurrence of certain infectious fevers under certain known conditions, as that of typhus in connection with the maladministration of armies in the East, coupled with the depressing emotions consequent on defeat. The numerous instances which occurred where no antecedent cases of the disease could be found, even when the circumstances were specially favourable to their discovery if they existed, were next noted; and, after some minor points had been discussed, the author assumed the

right of all who did not believe that each of the specific poisons was the result of a definite act of creation, to maintain that, if they had once arisen independently of antecedent cases, it was impossible to assert that what had taken place could never take place again. So far, Dr. Thorne had sought to avoid taking any side in the argument; but in the remainder of his paper he explained in detail the grounds which had led him provisionally to lean to the view that the property of infectiveness is, under certain circumstances, one capable of progressive development. In support of this opinion, he gave the history of some investigations he had made for the Local Government Board into outbreaks of diphtheria, and he explained how he had found cases of apparently simple non-infectious sore-throats somewhat uniformly spread over an area of several miles, whereas, at certain limited points in the same area, and at a somewhat subsequent date, the sore-throats in question were distinctly infectious, and in some localities had led by transmission through a series of persons to the development of well-marked severe diphtheria. In conclusion, he pointed out that such a view as he had maintained was not that of the development of a living organism out of matter independent of antecedent life, but rather the production by a process of evolution of that which gave to an already existing organism that property by which it became infective.—In the discussion which ensued, the PRESIDENT, Dr. BUCHANAN, Dr. CORFIELD, Dr. SAUNDERS, Inspector-General LAWSON, and Mr. NETTEN RADCLIFFE took part.

#### ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

WEDNESDAY, MAY 15TH, 1878.

S. J. A. SALTER, M.B., F.R.S., President, in the Chair.

*Necrosis of Superior Maxillary Bone, following the Eruptive Fevers.*—Mr. LYONS showed a patient (a young woman) who, when four years of age, had an attack of measles, from which necrosis involving the superior maxillary bone supervened. An operation was then performed, whereby part of that bone, consisting of the alveolus, extending from the right first temporary molar to the left canine, and part of the vomer and palate were removed; the disease also extended over the right ala. She first came under Mr. Lyons's notice a few months since, being then twenty years of age, and presented a most unprepossessing appearance through inability to close the right side of her mouth, owing to the contraction of the cicatrices, which drew the lip upwards. On March 18th, she was placed under chloroform, and the folds of mucous membrane connecting the cheek with the bone were carefully divided. The operation was so far successful that she was at once able to close her lips upon each other and allow an artificial piece, as well as an artificial ala, to be inserted with most satisfactory results as regards her comfort and personal appearance.

*On Some Forms of Trismus arising from Dental Irritation.*—Mr. GAINE read a paper on this subject. He prefaced his remarks by observing that some of these cases of trismus were very obscure in their origin, but the majority of them arose either from difficulty in erupting the wisdom teeth, owing to an overcrowded condition of the teeth generally, or to periodontitis or necrosis. The majority of the cases that had come under his notice occurred in young women, and were associated with hysteria; and in the diagnosis it would be well to separate those which arose from dental irritation from those mixed up with hysteria. The former, if seen at an early stage, were much more readily dealt with than the latter, though at the same time the local symptoms might be much more severe. In those cases arising from dental irritation, when the jaws were closed, recourse must be had to some anæsthetic in order to forcibly separate them, when some lesion would generally be found connected with one or more teeth, which should be at once removed. A notched wedge, or Mr. Maunder's screw-gag, was of great service in these cases, and the patient should be instructed to constantly wear it, and move it backwards and forwards at frequent intervals, until mobility was established. In cases of long-standing, Mr. Gaine found it the best practice to force a piece of tapered ivory between the molar teeth, and gradually work it on until the screw-gag could be inserted. The other class of cases—those connected with hysteria—was frequently difficult to diagnose; the closure of the jaws occurred suddenly, and many of the symptoms of tetanus were present. Mr. Gaine then related several cases of trismus, associated with this hysterical condition, which had recently come under his notice, arising from tooth-irritation. In all the cases that he had seen, he did not know that he could point to one that came on suddenly that was not more or less associated with hysteria—of course, alluding only to cases of trismus unconnected with tetanus. He believed it was generally an accepted fact, that spasm of some form or other affecting in nearly all

cases the masseters and pterygoids by what is termed reflex action was the cause of the muscular rigidity which had to be contended with. Nor was it only these muscles that were affected, but indirectly through the connections of the fifth nerve with the seventh nearly all the facial muscles sympathised; and frequently the glosso-pharyngeal nerve through the otic ganglion affected the muscles of deglutition. Mr. Gaine concluded by observing that he thought much light might be thrown upon the pathology of these cases, which were closely mixed up with hysteria, by a pathological investigation of the connection of these nerves with the sympathetic.—A discussion ensued, in which the PRESIDENT, Mr. W. A. N. CATTLIN, Mr. NAPIER, and Mr. S. H. CARTWRIGHT took part.—Mr. GAINE briefly replied.

#### HARVEIAN SOCIETY OF LONDON.

THURSDAY, MAY 16TH, 1878.

GRAILY HEWITT, M.D., President, in the Chair.

*Large Tumour of the Left Cerebral Hemisphere.*—Dr. HUGHLINGS JACKSON read a communication on a case of cerebral tumour, of which some account had been previously published. It occurred in a boy, who at eight complained of tremulousness of the right hand. This was in October 1876; he survived till May 1878. The tremulousness was followed by headache and then by vomiting, and ultimately by convulsions. Then, later on, the eyesight began to fail. He grew bigger. Hemiplegia gradually came on. Nystagmus appeared. A fit came on, when the left side was rigid. Later on, he complained of intense pain in the head, followed by a tetanoid fit, when there was well-marked opisthotonos; the limbs were all rigid, and the eyes were divergent, the left pupil widely dilated, and the right pupil greatly contracted. At the necropsy, a large tumour measuring three inches and a half from before backwards, and two inches and a half across, was found involving the left corpus striatum and crus cerebri, the corpora quadrigemina not being involved. The optic tracts were affected. Hemorrhage was probably the cause of the fatal fit. The pons Varolii and cerebellum were quite normal. From the slow onset of the hemiplegia, tumour was indicated, in addition to the other symptoms. The question was, what sort of an adventitious product was it? Probably a voluminous one. The growth of the head suggested this. It might have been a tumour of the middle lobe of the cerebellum from some symptoms. There was no aphasia or defect of voice. Hemorrhage from a tumour is often the cause of sudden death in these cases.

*The Effects of Position on Local Circulation.*—Mr. JOSEPH LISTER read a paper on this subject.—In the discussion which followed, Dr. HUGHLINGS JACKSON and the PRESIDENT both expressed their admiration of the views expounded, and the manner in which they were set forth; but said that time was required to digest the facts properly.—Drs. BURNEY YEO, AVELING, and FITZPATRICK spoke; and Mr. KNOWSLEY THORNTON told of the absence of secondary hemorrhage in Professor Lister's wards in Edinburgh during the time he attended them.—Professor LISTER replied briefly; and the meeting adjourned till the next session of the Society.

#### PATHOLOGICAL SOCIETY OF DUBLIN.

SATURDAY, MARCH 30TH, 1878.

EDWARD HAMILTON, M.D., President, in the Chair.

*Chronic Pleuropneumonia: Atheromatous Degeneration.*—Dr. FINNY showed the thoracic viscera of an old soldier, who had suffered from an abscess in the leg and another in the groin connected with the ileum. A basic systolic murmur, heard best at the right second interspace, and dulness on percussion over the upper part of the right lung, were the chief physical signs. After death, examination revealed the presence of chronic interstitial pneumonia, with cheesy deposit and bronchiectasis in the right apex. The right pleura was adherent, much thickened, and extremely cartilaginous. The aorta was dilated, and afforded an example of atheromatous change in its three stages. The heart, originally hypertrophied, was in a condition of fatty degeneration, owing to the extension of endarteritis deformans to the coronary arteries.

*Muscular Anomalies.*—Dr. KENDAL FRANKS brought forward examples of muscular anomalies. The pectoralis minor was absent on the left side, although the pectoralis major was present. The serratus magnus on the same side, in addition to its normal origin, arose from the costal cartilages and the sternum itself. There was likewise an abnormal development of the flexor sublimis digitorum. All these anomalies were on the left side of the body. On the right side, there were three pectoral muscles.

*Carcinoma of Abdominal Viscera.*—Dr. W. G. SMITH showed the abdominal organs of a man aged 57, who had suffered chiefly from increasing debility and incessant vomiting of large quantities of greenish watery fluid. The abdomen was distended, and there was some ascites. Solid tumours and nodules were felt over the abdomen. The urine was high coloured, and there was an excess of indican. A thick layer of subcutaneous fat existed in the abdominal wall, which was glued to the viscera by tough cottony adhesions. A large triangular mass of scirrhous occupied the situation of the omentum. It creaked on section. The liver was shrunken and ovoid in form. The kidneys and spleen were healthy. The pylorus, mesenteric glands, and peritoneum were affected with the scirrhous variety of carcinoma. The pylorus was the part first affected.

## ASSOCIATION INTELLIGENCE.

### EDINBURGH BRANCH.

THE annual general meeting of the above Branch will be held at 5, St. Andrew's Square, Edinburgh, on Tuesday, June 18th, at 4 P.M.: Sir ROBERT CHRISTISON, Bart., President, in the Chair.

CHARLES E. UNDERHILL, *Honorary Secretary.*

Edinburgh, June 4th, 1878.

### EAST ANGLIAN BRANCH.

THE annual meeting of the above Branch will be held in the Infirmary, Peterborough, on Friday, June 21st, at 11.30 A.M., in conjunction with the Cambridge and Huntingdon and South Midland Branches: THOMAS J. WALKER, M.D., President elect, in the Chair.

After Branch preliminary business at 11.30, there will be a general meeting about 12.15, when the President-elect will read an address; at the conclusion of which, he kindly invites members to lunch at his house before the next general meeting at 2.15 P.M., for papers, discussions, etc.

Gentlemen wishing to read papers, or to dine, are requested to communicate as early as possible with one of the Honorary Secretaries.

WM. A. ELLISTON, M.D., Ipswich, } *Honorary Secretaries.*  
J. B. PITT, M.D., Norwich, }

Norwich, May 14th, 1878.

### CAMBRIDGE AND HUNTINGDON BRANCH.

A COMBINED meeting of the above Branch with the South Midland and East Anglian Branches will be held at the Infirmary, Peterborough, on Friday, June 21st. The following arrangements have been made.

Separate meetings of each Branch for business at 11.30 A.M.

General meeting of the three Branches to hear the President's Address at 12.15.

Luncheon at One o'clock, at the house of the President—Dr. T. J. WALKER.

General meeting at 2.15, for papers, discussions, etc.; after which, should time permit, an inspection of the Cathedral and the adjacent buildings will be made.

It is intended that those members who are able should dine together in the evening.

BUSHELL ANNINGSOON, *Honorary Secretary.*

Cambridge, May 21st, 1878.

### BATH AND BRISTOL BRANCH.

THE annual meeting of the Branch will be held at the Mineral Water Hospital, Bath, on Wednesday, June 26th, at 4.30 P.M., when H. MAPSHALL, M.D., will resign the Chair to H. HENSLEY, M.D. The members will afterwards dine together at the York House.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, June 4th, 1878.

### MIDLAND BRANCH.

THE annual meeting of this Branch will be held at Lincoln, on Tuesday, June 27th: President—C. H. MARRIOTT, M.D.; President-elect, A. MERCER ADAM, M.D.

Members desirous of reading papers are requested to communicate with C. HARRISON, M.D., *Honorary Secretary.*

Lincoln, May 14th, 1878.

## THAMES VALLEY BRANCH.

THE next general meeting will be held on June 13th, at the Greyhound Hotel, Richmond, at Six o'clock.

Papers will be read by—

1. Mr. Balmanno Squire: The Use of Chrysothanic Acid.

2. Dr. Trouncer:

3. Dr. Atkinson: Vaccination and Revaccination.

Dinner at the above hotel at Seven o'clock. Charge, 7s. 6d. each, exclusive of wine.

F. P. ATKINSON, M.D., *Honorary Secretary.*

Kingston-on-Thames, May 13th, 1878.

## BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE sixth ordinary meeting of the session was held at the Museum and Library, Bristol, on Wednesday, May 29th; Dr. MARSHALL, President, in the Chair. There were present sixty-eight members and four visitors.

*Discussion on Alcohol.*—Dr. Fox opened a discussion by reading a paper on Alcohol in Health and Disease: a very interesting and animated discussion followed, in which Drs. Davey, Atchley, Fyffe, Brittan, and Goodridge, and Messrs. Batrum, Metford, Jessop, Stewart, and Carr took part.

## CORRESPONDENCE.

## THE ELECTION OF COUNCILLORS AT THE COLLEGE OF SURGEONS.

SIR,—As the official circular to the Fellows of the College of Surgeons of England has now been issued, and the election to the Council will take place in a month's time, will you allow me, as an independent Fellow, to point out to my fellow-electors one aspect of the annual election which I fancy is somewhat overlooked. There are no doubt many highly respectable Fellows, both in London and the provinces, who may fairly enough aspire to a seat for a few years in the Council of their College, but who lack the professional status and personal qualifications which are essential for the President, if he is to represent his College officially on great public occasions with dignity and honour. The first election of a councillor is, therefore, comparatively unimportant, at least *quoad* the presidency; but a re-election is a very important business, both for individual councillors and for the College as a whole. It is true, that the actual selection of a President rests with the Council and not with the Fellows; but we ought not, I think, to throw upon the Council the invidious task of passing by one of its own body, by neglecting our duty of re-electing only those who can with dignity fill the President's chair.

I beg leave to say that these remarks are not intended to have any special bearing upon the coming election, and that it is only from accidental circumstances they have not been put forward at an earlier date.—Yours obediently,

A FELLOW OF THE COLLEGE.

London, June 1878.

## THE WORK OF THE REGIUS PROFESSOR AT OXFORD.

SIR,—“Your Editorial Contributor” does not yield to “Spectator” in his jealousy for the medical school of Oxford; but he thinks that the prospects of that school will not be diminished by the observance of fairness and courtesy. “Spectator” says that Dr. Acland has “converted” a number of paid medical offices into sinecures; that he deliberately obstructs and prevents medical teaching in its essential branches; and that this official “has destroyed in the past” the medical school, etc.

Now, is this true? Or is it rather true that Dr. Acland took these “paid medical offices” as he found them, and that he can scarcely have destroyed that which seems never to have existed?

And is it not rather true that Dr. Acland has done ten times the work of any of his recent predecessors in the cause of medicine as he regards it? And, finally, that, although that work does not include the duties which “Spectator”, like myself, would desire from him, yet he has done work which not only he himself, but every physician in Oxford, and also the Professor of Anatomy at Cambridge, believe to be far more useful for the attainment of that end which we all desire; namely, the higher development of the medical art in this country. That an official is industrious in a wrong or incomplete method, and that he is badly or imperfectly advised, is one thing; it is another thing to represent him as a mere sinecurist and a mere marplot.—I am, etc.,

YOUR CONTRIBUTOR.

## MEDICAL ENDOWMENTS AT OXFORD.

SIR,—The advocates for the revival of the lost medical school at Oxford are under a heavy debt of gratitude to the JOURNAL for advice, support, and an opportunity, not only of ventilating their grievances, but also of establishing concerted action. They proved, however, to be but a miserable minority of even the medical graduates of the university, and their efforts and your and their representations have only ended in defeat and disappointment, the more mortifying when we regard the very different attitude towards medical education of the University of Cambridge. *Non equidem invideo, miror magis.* I shall not dwell upon the circumstances of our defeat, partly because it would only give rise to reproach and recrimination; but our feelings on the subject are none the less strong, and certainly are not likely to grow weaker, when we read in the JOURNAL and elsewhere, week by week, incisive exposures of the fallacies and misrepresentations that were urged against the feasibility of our project.

The report of the University Commission is the death-blow to our hopes, when it decides against “the establishment of a practical school of medicine in Oxford”. The Commission was led to this conclusion by the evidence and opinion of certain distinguished physicians and surgeons. I do not impugn the motives of their evidence, when I suggest that the Commission might well have considered and made allowances for the fact that these most weighty witnesses were closely connected with the great London hospitals by past or present ties, and could not be expected to regard without prejudice, much less with favour, a proposal which implied that even the elements of medicine and surgery could be with advantage studied elsewhere than in their own wards and class-rooms. I entirely acquit them of any paltry jealousy of present or future provincial schools, but not of an unconscious and very pardonable belief that it would not be less than a sin to allow Oxford and Cambridge men to forego the rare privilege of being their pupils and admirers.

Some, however, of the recommendations of the report seem proofs that our movement has not been entirely without fruits. The Commission recommends the provision of a reader in human anatomy with a stipend of from £250 to £300 *per annum*. That is a step in the right direction, and may lead eventually to some further steps which seem logically and practically consequent upon it. That, however, bears rather upon the future than the present. But another recommendation, to which I urge particular attention, is of immediate consequence to the profession, and yet will most certainly fall to the ground, unless a strenuous effort be made for its fulfilment. This is in favour of “the foundation and endowment of scholarships or exhibitions, tenable after a certain fixed period of residence in the university, for students in any special branches of study (including subjects which do not fall within the ordinary university course, such, for example, as medicine), which may be usefully promoted by such encouragement under conditions properly adapted to make their enjoyment dependent upon the *bonâ fide* prosecution of such studies”. This recommendation is even now engaging the attention of the resident Fellows, who have virtually in their hands the disposal of the immense revenues of the colleges. They mean well; they have high ideals of education; but they know absolutely nothing (*ex parte crâle*) of the requirements of medicine (how should they?), and are, moreover, fatally indifferent to the whole subject of professional education, whose clerical phase has always been their bugbear. They will, however, have to deal with the subject as best they may, and you may be sure that the legal and clerical views of professional education will be fully and eloquently laid before them, and their necessities amply provided for. But the interests of medical education will, I fear, be simply ignored; no member of common-room knows or cares about them; the medical profession, as an abstract entity, is decidedly at a discount among the classes which call themselves cultivated. Barristers and parsons are expected to be more cultivated than the average laity, and, as a rule, are so. No one expects a doctor to possess any knowledge or show any interest in anything which does not serve to put money in his pocket, and it must be confessed that that expectation is seldom disappointed. Doctors are generally supposed to be raising a cry for university education; in the sense that every practitioner is anxious to have the right of putting M.D. after his name; but that no one is willing to go through the ordinary course of university education, which, in England at any rate, is the condition of a degree. I do not think that is so, but believe that the profession is conscious of some of its failings, and in that belief call upon it to assert its just rights and claims upon the university; for I must repeat that, unless pressure be brought to bear upon the colleges by the profession from outside, law and divinity will devour the share of the spoil that ought rightly to fall to medicine. Let it, then, be clearly understood that, while the university is advised not to have a school of prac-

tical medicine in Oxford, it is recommended to offer pecuniary encouragement to the study. To carry out this recommendation effectually, provision should be made to afford help to deserving men at each of the following stages:—1. While they are at Oxford going through the usual course of study there; 2. While they are medical students in London or elsewhere; 3. While, after graduating in medicine, they are for some time doing good but generally unpaid professional work at the hospitals, and as yet unable to depend upon their profession for subsistence. To make requisite provision for each of these stages, I would suggest the institution at Oxford of—

1. Additional scholarships in natural science. (This is to be done, I hear.)

2. Studentships in medicine of the value of from £100 to £150 *per annum*, and tenable for five years. Candidates for these must be graduates in arts and intend to become *bonâ fide* medical students at some recognised school; their continued tenure might be made to depend upon the production of certificates of industrious study at their medical schools. They should be awarded for proficiency in any of the subjects of the final schools for honours at the university. Among these are biology, chemistry, and physics; but there is no reason why the students in medicine should not have been previously distinguished in other branches of knowledge, such as law, mathematics, philosophy.

3. Fellowships in Medicine of the value of £200 *per annum*, and tenable for five years. Candidates must be graduates in medicine. They might be awarded for proficiency in any one of the following subjects: *a.* Medicine; *b.* Surgery; *c.* Obstetrics; *d.* State Medicine.

In all cases, there should be limitations of age, university standing, and against marriage. Provision should be made to defer elections in case of insufficient merit among the candidates of any year. Every year, at least four Studentships and two Fellowships should be open to competition among the many intending medical students which such prizes would attract to Oxford and the profession. This would involve an annual expenditure of from £4,000 to £5,000; for I do not, of course, include in this sum the additional scholarships in science, as they are demanded in the interests of general, and not merely of medical, education. The sum is not a large one for a rich university to devote to the poorest of the learned professions; indeed, it is but a tithe of what is spent upon the legal and clerical professions. The colleges and university are debarred by the terms of the report from doing anything for medicine but endowing it. Whether they do this depends upon the action of the profession at large, but more especially of its corporate bodies and great organisations, to whom I most respectfully suggest the necessity of a prompt vindication of the interests of the profession. The governing bodies of each of the colleges should be severally invited to carry out an express recommendation of the Commission in a manner worthy of the university and of the profession of medicine by contributing to a general fund for this purpose, or by founding studentships and fellowships of medicine in connection with their respective colleges, as may seem best to them.

I hope this communication may invite both comment and criticism. Details have been of purpose omitted, as the scheme is merely tentative and designed to elicit expressions of opinion from others, and, above all, to lead to some action. I cannot, however, refrain from hoping that some such scheme may rid us of some glaring evils, such, for example, as the melancholy necessity, destructive of independence and real work, under which the junior members of our hospital staff labour of becoming boarding-house-keepers, half bear-leaders, half crammers, or lecturers on botany; the enforced retirements, owing to poverty, of some of the most promising members of the profession from competition for the ill-paid hard-worked posts of the permanent staff of hospitals, and the consequent appointment of inferior but richer men. In fact, the end of the proposed scheme would be *la carrière ouverte aux talents*.—Your obedient servant, G. P.

#### THE TITLE OF DOCTOR.

SIR,—Hardly a week passes but there is in your columns some reference to that now doubtful decoration of *Doctor*. If the general opinion of the profession could be known, it would be seen that the once regarded distinction is now verily held in low esteem; and deservedly so. In these days, it is no proof of academic or professional excellence. It has become so commonised that it carries no weight with it, either amongst the public or amongst ourselves. The people generally cannot judge between the genuine and the spurious article. The *doctorates* of Oxford, Cambridge, London, and Edinburgh cannot be known from those conferred by the smaller Scotch universities—from those in a summary way procured in Germany—nor from the still more objectionable degrees which are chiefly vended in the distant States of America. Again, the licentiates of the Colleges of Physicians of Lon-

don or Edinburgh not unfrequently pretend that they are *Doctors*. I any one glance at the pages of the *Medical Directory*, he will perceive how large a number of the general practitioners have, from one place or another, procured this title. Homeopaths, hydropaths, electro-galvanists, sanatorium proprietors, corn-cutters, itinerant lecturers, and so-called teachers of philosophy must all have the affix. Quacks and charlatans regard its use as favourable to their various enterprises. In the poorer parts of our cities and large towns, the *Doctor* is rendered conspicuous on huge brass-plates, and proclaimed in grand gold letters in association with gorgeous lamps and brilliant bull's-eyes. During the last half-century, it has been so degraded and dragged through the mire, that it now rather lowers than elevates our great calling. There are many amongst our ranks who have, and justly, a lofty conception of our high vocation, and are aggrieved that the medical profession does not in the public mind hold place with the law and the church. The debasement of the *doctorate* is, and with much show of reason, regarded as one cause that medicine occupies a lower platform.

A distinguished Fellow of the Royal College of Physicians, when speaking to me lately on this subject, remarked: "The surgeons socially have a great advantage over us. They have not to always use the now equivocal title. They can pass on in society as plain *Misters*." Not long ago, another well-known Fellow with a few friends left London for a day's recreation. He soon felt that his enjoyment was about to be marred. One of the party would continually *Doctor* him, although the former turned and said, "Now, my dear fellow, pray do drop all this *Doctoring*; I have come out for a little relaxation, and let me have the pleasure, for at least one day, of thinking I am a gentleman!"

Clergymen in some few instances adopt the *Doctor*, but when they do so such are generally in connection with some scholastic establishment. It is true, that Irish barristers also take up this *Doctorate*. When they come to the English bar, they have the good taste to put it down.

I know it to be the opinion of many, and of some prominent names, that the title of *Doctor* has with social changes lost its value; that the medical profession would rather gain than lose in importance with its abolition; and that for its members to be merely known as physicians and surgeons, and addressed as *Misters*, like barristers and solicitors, would be a benefit to all and a loss to none.

April 27th, 1878. I am, your obedient servant, F.R.C.P.

#### YELLOW FEVER.

SIR,—Since my letter on Yellow Fever appeared in the *Times* of April 23rd, I have had communications from medical men requesting me to "ventilate the subject", and perhaps this can be best done by relating some facts and opinions connected with this fatal disease in the BRITISH MEDICAL JOURNAL.

The Surgeon-General of the Colony, in his evidence before the Commission of Inquiry into the Epidemic of Yellow Fever in Demerara in 1866, stated "that there is no similarity between intermittent and yellow fever, neither has remittent fever any connection with the disease"; and the late Professor Parkes, certainly the most careful and reliable authority on such matters, says "that the progress of inquiry shows that true yellow fever is distinct from malaria and paroxysmal fevers".

The Demerara inquiry corroborated the opinion that it is a disease of towns, barracks, cities, and parts of cities. It was stated in evidence that, in 1861, in consequence of yellow fever being present near the barracks, the men were removed to the country. "On the 3rd June, 1861, the whole of the white troops, consisting of two companies of the 21st Fusiliers, were removed into camp at Belfield, a few miles distant. On the 13th, a case of yellow fever occurred in the camp; on the 18th, two; on the 20th, three; and another a few days afterwards, making altogether seven cases. With one exception, they were of a mild type, and all yielded to treatment. There were no other cases during the remainder of their stay at Belfield". The men remained in camp until the 18th of the following January; they were, therefore, there during the months—July, August, and September—generally supposed to be the most unhealthy in that tropical climate.

The beneficial results of removal from barracks to the country and the bad consequences of delay were illustrated in an epidemic of yellow fever a few years ago in Barbadoes. "In the cases of the 21st Foot and 1st West India Regiment—the former were placed under canvas in the country at a place called Gun Hill, although in the rainy season, and escaped the disease. The officers and European non-commissioned officers of the latter were, at their urgent solicitation, allowed to remain in their comfortable barracks to escape the risk to their health of

removal to tents, and they suffered a severe mortality" (*Report of Commission*, page 8, and *Appendix*, page 39).

The late Dr. Parkes says that the course of inquiry makes it more certain that yellow fever, like cholera and typhoid fever, is a fecal disease. In the Demerara epidemic of 1866 amongst the white troops, it was proved in evidence that the garrison-trenches which received all the excreta from the barracks, from latrines placed over them, had not been properly cleaned out for upwards of four years, and that the men who suffered from the disease had been employed working along the margin of these trenches removing grass, etc. The Commission reported: "The garrison grounds are intersected by about four miles of garrison-trenches. They receive the whole of the sewage and fecal matter of the garrison. On account of the dead level of the land, it is most difficult to keep these open trenches in proper order. The trenches are flushed with salt water, which is largely charged with alluvial detritus, and out half-an-hour after every high tide, and are left half full for about three hours, when it is discharged into the river by an outlet sluice. We consider the principle by which the whole fecal matter is retained floating in these trenches from tide to tide radically bad. The only thorough remedy is the introduction of the dry earth system." (*Report of Commission*, page 6.)

The course of inquiry tends to show that yellow fever, when once introduced, may spread in temperate and colder climates, and, to quote again Dr. Parkes, who shows that the disease "has prevailed at Newcastle in Jamaica, 4,200 feet; at Nalapa, 4,330 feet; and on points of the Andes as high as 9,000 feet".

These facts then—that it is a disease of houses, towns, cities, and parts of cities; that fecal matter has, in all probability, largely to do with its origin; that it can spread in a colder climate than was formerly supposed—show how necessary it is that all medical officers of health and sanitary authorities should be well acquainted with the nature of yellow fever, so that they may be able to deal in a practical way with any cases that may arise in this country. In order to prevent the spread of these diseases, it is, before all, necessary to have clear views as to the mode of propagation.

If the fecal origin of the disease, supported as it is by so eminent an authority as the late Dr. Parkes, be correct, it shows what care should be taken in this country when a case occurs similar to the one recently reported in one of the squares in Belgravia, for contamination of any water-closet or latrine might lead to the spread of the disease, and in the most fashionable district of London.—I remain, sir, yours obediently,

GEORGE A. HUTTON,

Surgeon-Major, Half-pay, late Rifle Brigade.

Lamington, May 14th.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### SUGGESTIONS FOR THE SANITARY REGULATION OF DAIRIES.

IN consequence of the severe outbreak of typhoid that occurred last year at Glasgow and was traced to a single dairy at Stonehouse, a meeting was held and presided over by the Lord Provost, when a resolution was unanimously agreed, "That it is desirable that a general measure of legislation should be passed with regard to the regulation of places of milk-supply"; and a Committee was appointed to take steps for carrying it out. A sub-committee, consisting of Dr. Anderson, the Professor of Clinical Medicine; Mr. Sheriff Spens; Mr. McCall, the Professor of Veterinary Medicine; Mr. Miller; and Mr. Leadbetter (Chairman), were appointed. The attention of the Committee was specially directed to two points; viz. diseased milk from foot-and-mouth disease, etc., and infected milk. They considered that the risk to the public is greater from the latter than the former. They therefore drew up certain suggestions in the form of a Bill for the consideration of the Council containing twenty-two clauses. These briefly are, that every milk dealer shall be registered by the local authority, whether he sell milk by wholesale or retail; that the medical officer of health shall keep a register of places of milk-supply; that the medical officer of health or inspector shall inspect all premises used for milk-supply, and, if not satisfied, no certificate be granted—subject, however, to an appeal to the sheriff; the medical officer to have power to inspect at all times, and to draw up and issue by-laws for enforcing efficient sanitary arrangements of such places. It is then proposed that every person so registered shall communicate to the local authority the existence of any infectious disease in his household within

twelve hours of its occurrence; and that every medical practitioner who shall attend such a case in a place of milk-supply must give information to the medical officer of health, for which he shall receive a fee of half a guinea; further, that no person recently recovered from a contagious disease shall handle, sell, or deliver milk; and that no master shall employ such a person until a certificate shall have been given that he is free from the disease. The penalties proposed are very heavy, as any person delivering or allowing to be delivered milk after a prohibition from the medical officer would be liable to a penalty of £30; for a second offence, not less than £50. Provision is also made for the compensation (not exceeding £50) of those who are prohibited from selling or despatching milk, provided there were no fault on the part of the person registered. The Act would be restricted to Scotland.

This is an important proposition to have proceeded from such a Committee, as it shows that a necessity for some such action is gradually permeating the minds of others than medical officers of health and medical men. The proposed Bill cannot be found fault with for want of thoroughness, but would certainly have gained in weight if it had been approved by the Glasgow Town Council, inasmuch as the compensation will have to be paid by the local authority. There should also have been a clause to the effect that the penalties recovered be payable to the local authority; otherwise they will have all the expense of carrying out the Act if passed, and none of the sums obtained from the offenders. The Bill is a considerable advance on anything yet proposed, and is worthy of efficient support from the profession and the public.

SIR.—Having read the account of the correspondence between Mr. Buck of Newport, Essex, the Board of Guardians, and the Local Government Board, I would like to trouble you to give your opinion on a somewhat similar case that happened to me a short time ago.

Last November, I received an order from the relieving officer to attend a patient who was suffering from the effects of pregnancy, and was within six weeks of her confinement. About a fortnight after receiving the order, she applied for another for me to attend her in her confinement. This, however, was refused; consequently, thinking she would have to pay, did not send for me. I was also required to attend her after her confinement. I may also add, that her husband was on the sick-list at the time, and was receiving parish relief, and continued doing so till a week or two ago.

If I had attended this patient in her confinement, could I, legally, have claimed the usual fee?—I am, sir, yours truly,

GEORGE SEARANCEKE,

Medical Officer and Whitford District, Holywell Union.

Gronant, March 5th, 1878.

\*\*\* We consider that if this woman had sent for the medical officer to attend her in her confinement, he would not only have been justified in at once attending, but liable to censure if he had refused so to do, and therefore could have legally claimed a fee. The guardians, by sanctioning the order of the relieving officer for medical attendance prior to her confinement, had *de facto* constituted her a pauper, and could not justifiably refuse her subsequent application. The case is still further strengthened by the sickness of her husband, and the fact that he was at the time in the receipt of parochial and medical relief. It is a very apt illustration of the unfair way in which some boards of guardians act towards their medical officers. We would advise that our correspondent should lay the facts before the Council of the Poor-law Medical Officers' Association. The case of Mr. Buck and this one form a very good text on which a letter to the Local Government Board may be framed. Those who desire to read the law on this subject are referred to *Glen's Consolidated Orders*, foot-note B, pages 160, 161, and 162.

### SUPERANNUATION.

IN reply to "An Old Member", we state that it is much to be regretted that he should not be better posted in the questions relating to Poor-law medical officials and superannuation than he appears to be, since this indicates great apathy in following the action of the Poor-law Medical Officers' Association, which has obtained from the Legislature an Act (unfortunately only permissive), whereby boards of guardians can superannuate worn-out medical officers. In order to obtain superannuation, he must be able to show that he has had twenty years of service; that he is above sixty years of age; that he is incapacitated by infirmity; that he has obtained a certificate from the Poor-law inspector of his district to that effect (easily obtained by application); and that he has resigned his appointment. As regards the latter, we would advise our correspondent not to resign until he has sounded his board and learnt whether they are disposed to grant superannuation or not. Many medical officers have been superannuated.

DRAYTON RURAL.—This is the first report by Dr. Sandford, and he states that a considerable amount of sickness had occurred in the vicinity of Market Drayton; typhus and typhoid fevers prevailing in the early part, and scarlatina in the later part of the year. The typhus outbreak was introduced by a stranger, and spread to a considerable extent, owing to the insanitary conditions under which the patients were placed; and scarlatina also spread, owing to want of proper isolation of the sick and disinfection of the clothing, etc. The birth rate was 32.3 and the death-rate 17.0 per 1,000 population.

## MILITARY AND NAVAL MEDICAL SERVICES.

## MILITARY, VOLUNTEER, AND CIVIL SURGEONS.

SIR.—In your issue of the 11th instant, "Militia Surgeon" reports his individual hardship, which is similar to many other militia medical officers, and whose battle was fought in Parliament by Dr. Playfair and other gentlemen, and lost; for Mr. Hardy was determined not to yield. But "Militia Surgeon" has another grievance: probably he forgets, as Mr. Hardy has broken faith with militia surgeons once, it may be done a second time, in this manner, by declining to allow the surgeon the usual year's pay on disembodiment of their regiments; and it would be well if the medicos had that assured to them before they went on embodied service.

I was sorry to see in the same issue that a volunteer surgeon was inclined to accept Dr. Munro's circular, as by giving gratuitous service injury is done to army surgeons, whose profession it is, and whose wrongs will never be redressed if Government be backed up by civil practitioners or volunteer surgeons, who ought rather to support their ill-used brother medical men in the army and navy.—I remain, your obedient servant, M.D.

## ARMY MEDICAL SERVICE IN INDIA.

SIR.—Your correspondent "Perick", in the JOURNAL of April 13th, writes to point out that the medical officers who joined the army on the first invitation by the new Warrant—*id est*, that of April 1876—find themselves in very much the same condition that the subjects of a certain king of whom we read in Bible history were in: in other words, they asked more and were given less. They would not join under the Warrant that secured to them substantial advantages, and also the pay in India of 317 rupees, which, when granted, was worth about £31 14s.; so a new warrant was issued, which, he informs us, took away many of those substantial advantages, and it at the same time only granted the same number of rupees, now worth as a money value only £25 14s. 9d., and, compared with the purchasing power ten years ago, much less. In answer to all this, I have one question to ask him, or if Perick be not within hail of the penny postage, you or any of your numerous readers: What is the number of the paragraph in the Royal Warrant of April 1876 that refers to Indian pay, as I am unable to find any such clause in it? I am aware there is a printed paper being circulated called "Extracts from the Royal Warrant of April 1876", wherein it is stated the pay will be £31 14s.; but, as far as I can see, it is not a correct statement; as no such thing existing in the Warrant, it cannot be an extract. The Warrant provides for £250 a year and extras; and as those extras in India have been 166 rupees a month, the Warrant provides for 374 rupees a month, and for what reason the right pay is withheld I can find no one to inform me; and those who are content to serve on 37 rupees a month less than they are entitled to, appear to me to differ in opinion from one who considers himself

NOT A FOOT.

## OBITUARY.

## JAMES M. CUNNINGHAM, M.D.

WITH regret we have to announce the death of Dr. James M. Cunningham of Hailsham, Sussex, in his seventy-fifth year, which event took place on Wednesday, April 24th, from acute pulmonary congestion and hæmorrhage. He entered the Royal Navy at an early age, but subsequently turned his attention to medicine, and took his degree as M.D. at the University of Edinburgh. After two years' practice at Whitstable, he removed to Hailsham, where he remained forty-five years, until his death, highly esteemed. He was an old member of the South-Eastern Branch of the British Medical Association, and at the time of his death was a Vice-President. He was medical officer of the parish, and also of several benefit societies in the neighbourhood, and also Assistant-Surgeon to the 3rd Sussex Artillery Volunteers. He was an enthusiastic member of the Masonic fraternity, by the brethren of which he was held in the greatest esteem and veneration, having attained the highest honours in the province in craft, caputular, and mark masonry.

## DAVID MANSON, M.D.

DR. DAVID MANSON was the fourth son of the late Mr. Manson of Fingask, who was for many years Manager of the British Linen Bank at Aberdeen. He was educated in that town, and became a graduate of the University, where, having passed through his medical curriculum with distinction, he obtained the degree of M.D. in 1872. He shortly afterwards went to Amoy, and very recently removed to Foochow; and got into excellent practice in both places among the European residents. He died at the latter place on the 1st of April, from sunstroke, aged only 30, deeply regretted by his relatives and numerous friends in Aberdeen.

**VOLUNTEER SURGEONS.**—The following volunteer surgeons, having undergone the requisite examinations, have been granted certificates of proficiency, entitling their respective corps to additional Government grants: Acting Surgeon W. A. Renshaw, M.D., 28th Cheshire R.V.; and Surgeon G. E. Corrie Jackson, 45th Middlesex R.V.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, May 30th, 1878.

Aldin, Ebenezer Wenham, Oxford  
Castle, Hutton, Newport, Isle of Wight  
Homes, James, Ledbury  
Hughes, Thomas Montgomery, 175, Kennington Road, S.E.  
Lighton, Henry Alfred Hamilton, Ross  
Lynn, Edward, Woolwich, Kent  
Michael, Henry James, Colchester  
Watson, Evan John, Durham

The following gentlemen also on the same day passed their primary professional examination.

Hardy, Henry Louis Preston, London Hospital  
Jones, Arthur Lloyd, London Hospital  
Way, Alfred Cox, Middlesex Hospital

In the list for March 7th, Frederick Enos Fenton, St. Mary's Hospital, should have been St. George's Hospital.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the usual monthly examinations for the Licences of the College, held on Tuesday, Wednesday, and Thursday, May 7th, 8th, and 9th, the following candidates were successful.—For the Licence to Practise Medicine: previous examination.

Bartholomew, Isabella

Final examination.

Clark, Ann Elizabeth Sweeney, Terence Humphrys

For the Licence to Practise Midwifery.

Clark, Ann Elizabeth Sweeney, Terence Humphrys

Hyne, Frederick Alexander

## MEDICAL VACANCIES.

The following vacancies are announced:—

**KENT AND CANTERBURY HOSPITAL.**—Physician. Applications to be made on or before the 28th instant.

**LONDON FEVER HOSPITAL.**—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance.

**MANCHESTER ROYAL INFIRMARY, DISPENSARY, AND LUNATIC HOSPITAL.**—Ophthalmic Surgeon. Applications to be made on or before the 25th instant.

**MIDDLESEX HOSPITAL.**—Assistant-Physician. Applications to be made on or before July 2nd.

**ROYAL HOSPITAL OF BETHLEHEM.**—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments. Applications to be made on or before the 25th instant.

**SOMERSET COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £120 per annum, with board, residence, and washing.

**TOWNSHIP OF MANCHESTER.**—Assistant Medical Officer. Salary, £140 per annum, with furnished apartments, washing, attendance, etc. Applications to be made on or before the 19th instant.

**WEST BROMWICH DISTRICT HOSPITAL.**—House-Surgeon. Salary, £30 per annum, with board, residence, and washing. Applications to be made on or before the 25th instant.

**WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.**—House-Physician. Salary, £100 per annum, with board, washing, and apartments.—House-Surgeon. Salary, £100 per annum, with board, washing, and apartments. Applications to be made on or before the 24th instant.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

## MARRIAGES.

**JACKSON—BARNES.**—On the 5th instant, at St. George's, Hanover Square, by the Rev. Charles Sedley Hagreen, Vicar of Staunton Long, cousin of the bride, assisted by the Rev. Capel Cure, Rector of the parish, Ernest Carr Jackson, of 71, Harley Street, Cavendish Square, eldest son of the late Thomas Carr Jackson, F.R.C.S., to Ada Constance Sedley, younger daughter of Robert Barnes, M.D., F.R.C.P., of 31, Grosvenor Street, Grosvenor Square.

**WALTON—LEAN.**—On the 4th instant, at the Registrar's Office, Lambeth, Surrey, Walter Thomas Prideaux Walton, M.B., Edinburgh, to Mary, third daughter of the late Francis Lean, R.N.—No cards.

**PRESENTATION TO DR. MORTON.**—This gentleman was last week presented by his friends in Castleblayney and its neighbourhood with an address, and a purse containing two hundred guineas, on the occasion of his leaving that place to reside in Nenagh. The address stated that, in losing him as their medical attendant, they would miss the clear-sighted skill and watchful attention which many of them had learned to value in time of sickness, and they would deeply feel the loss of his vigilance which he invariably exercised for good; while his example of uprightness and consideration for others, especially the sick poor under his charge in the Castleblayney Dispensary District, had gained for him universal respect and esteem.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

#### PURCHASE OF PRACTICES.

**SIR,**—The point raised by "Doubtful" in the **JOURNAL** of May 25th involves so many important considerations, that it cannot be dealt with by a mere affirmative or negative. It is important to remember that what is bought and sold is not an annuity, neither is it a business in the same sense as a shop or hotel. It consists essentially of an *introduction* to patients, and is peculiar in this important particular—viz., that the goodwill, as it is called, is for the most part vested in the *person* conducting the practice, and not in the *place* where it is carried on. Hence the more personal the practice becomes, the more unsafe it is as an investment; and, in fact, in every case where the practice depends entirely upon the high personal and professional reputation of a particular man, it cannot be transferred to another. In the vast majority of cases, however, a general medical practice is not of so purely personal a nature, and is, as a rule, perfectly transferable to a suitable successor; and facts and experience fully justify the assertion, that failure in succession almost invariably arises from the unfitness of the purchaser for the sphere he seeks to enter, and is not due to the want of good faith on the part of his predecessor. Cases of so-called "swindling" are not common, and when they do exist, are due either to the cause mentioned, or to want of due care and precaution in investigating the genuineness of the practice before purchase. The value of the practice can easily be ascertained by a full investigation, conducted upon certain principles well known to experts, who, moreover, can frequently supplement the statements of the vendor by valuable information derived from independent and reliable sources. The cases of "swindling" are mostly heard of in connection with private sales; and those who are the victims are those who want something exceptionally good far below the market value, and those who have too much confidence in their own opinion to take the advice of men specially skilled in such negotiations. If the preliminary investigation prove satisfactory, the investment may be considered safe, provided the purchaser be adapted to the connection to which he seeks to be introduced. Of course, the income cannot absolutely be guaranteed; for, if so, then the market value of the practice would be higher than that of an annuity, inasmuch as the latter ceases with the life of the annuitant, whereas the former has a considerable saleable value after death. The successor could not buy at the price if there were absolutely no risks; but these are reduced to a minimum if he be a steady, prudent, and industrious gentleman of average professional ability and good address. Such men rarely fail. The long permanence of a practitioner in a particular locality is of course a guarantee of the genuine nature of the practice; but it must not be overlooked that in such a case part of the connection is essentially of a personal character, and requires much tact to secure to a successor. Finally, why cannot a man succeed equally well by commencing "on his own account", without purchasing? In rare cases this may be possible, but experience is wholly opposed to such a proceeding. The essential condition of success is a rapidly increasing locality, uninfluenced by the reputation of any neighbouring practitioner; and the man who thinks it depends solely on his own personal skill and character deceives himself. It may be said, as a rule, that the plan is a failure, except in the East End of London, the Black Country, or the manufacturing districts in the North of England, where the densely populated districts offer special opportunities for success. The failures of medical men engaged in these attempts in the suburbs of London form a voluminous but melancholy history. It may therefore be safely asserted that, with due care, the purchase of a medical practice or partnership is not only a safe but a lucrative investment, but is, with the exceptions above quoted, the only satisfactory way of commencing practice.—Yours faithfully,  
J. GREGORY LANGLEY, M.B. Lond., M.R.C.S.  
30, Lincoln's Inn Fields, W.C., May 1878.

**SIR,**—In last week's issue of your paper, a correspondent inquires whether it is safe to buy a practice? To such a very vague interrogation it is scarcely possible to give any but a very indefinite reply. The chances in favour of a purchaser depend almost entirely upon personal qualifications and experience. Where one man will walk into a poor practice and succeed, another may purchase a first-class one and utterly fail. Patients are not to be bought and sold so easily as some seem to suppose. From the tenor of your correspondent's letter, I should assume him to be but recently qualified and somewhat nervous as to his own capabilities; and under these circumstances it would be wise for him to abstain from purchasing a practice altogether, except under very favourable circumstances. If he can meet with a really *bona fide* unopposed practice, which has not been made public property by constant advertisement by numerous agents, he might do worse than purchase, provided of course he can get a long introduction; but let him beware of practices *made* to sell, and which are constantly being advertised as "opportunities rarely met with", or to be "disposed of" on "very easy terms", etc. A good article will always ensure a fair price. By all means, if he can do so, let him wait his opportunity of purchasing a share in a really good practice, or be content with an assistantship with a view to the same. If he go to an agent, let him be careful to whom he goes, and to select some firm that will really look after his interests, and not recommend a bad investment simply to get their own commission out of the seller—a practice, unfortunately, frequently employed.—I am, sir, your obedient servant,  
FIDES.

#### SUDDEN ARREST OF THE HEART'S ACTION.

**SIR,**—A letter on the above subject in your number of May 25th brings to my recollection a case which occurred in my practice about ten years ago. M. H., able seaman, aged 23, was found dead in the water-closet, whither he had gone shortly after dinner. He had fallen forwards from the seat, with his hands resting on the floor. The body was minutely examined, from the brain to the pelvis, on the succeeding day, about twenty hours after death. The only abnormal appearance existed in the heart. This organ was in a state of most rigid general spasm, and in none of the cavities, right or left, was there a single drop of blood, while the adjacent large venous trunks were swollen and gorged up to their junction with the right auricle. There was no degeneration of the cardiac structure whatever. The stomach contained an enormous amount of solid food in an undigested state, and was so large as to press forcibly against the diaphragm. The size of the organ caused much surprise: it appeared to contain not less than treble the amount of even a heavy dinner.

Death was attributed to "spasm of the heart", induced probably by the pressure of the overloaded stomach against the diaphragm, intensified by the straining at stool. The man had been in good health previously, and had never complained of his heart.—Your obedient servant,  
R. N.

**NOTICES OF Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.**

#### UNIVERSITY EXAMINERS AND EXAMINATIONS.

**SIR,**—The discussion of the title of M.D. still progresses, and yet the solution appears to me most simple, at least for the future. Why do not all London students graduate in London? I think you have given the explanation in your **JOURNAL** at page 757, where you say: "Many teachers must be sorely perplexed in their endeavours to be at the same time honest to themselves, and yet to teach *such virtus* as are likely to satisfy examiners." Is it possible to write a greater satire on examinations? "views likely to satisfy examiners"! I believe the observation is perfectly appropriate. When I passed in Edinburgh in 1834, a man was ploughed for ignorance only; he might be a Mahomedan or a Puseyite, or a homoeopathic, or a Brunonian, or a Cullenite. He was only required to give the facts and arguments on each side of any position. I remember to this day the amused expression of old Alison when I asserted the force of the *sy stole* to be equal to one hundred and eighty thousand pounds, and quoted Dorelli; and he requested me to give the reverse opinion, and I was forced to confess that Keill put it at eight ounces, and was an equal authority, and had to give the opinions of Senac, Tabor, Sauvages, and Bernoulli, all more or less against me. In those days, if a man knew his work he might hold what opinions he pleased. But then the examinations were more or less public, at least two examiners being present. They extended over four hours, and were entirely oral, so that a student could not be severely bullied.

I have had four sons who have graduated respectively at Cambridge, at Edinburgh, at Oxford, and Dublin, and two have tried to pass the matriculation of the University of London and have failed. They have failed, however, in good company, as the senior boy of Harrow was unsuccessful at the same examination. All my sons were educated at public schools, ostensibly for Oxford, but two went afterwards to private tutors for the "ologies" for London. Curiously enough, in one instance my son's private tutor told me it was always doubtful if any man would pass the London matriculation; but as he was so very strong in natural philosophy, and must get so many marks in that (and of course he was so far above the average in classics), he would probably get through. He was ploughed, however, on natural philosophy, his strong subject; in fact, he had not learned "such views as are likely to satisfy examiners".

Now for the remedy: nothing more simple. Require that all papers be preserved, not thrown out of the window of a railway carriage. Secondly, let each candidate be required to give the name of his tutor. Such tutor shall have permission to read the papers of all the men who have passed, and also those of his own pupils who have not. Let the examiners sign their names to each paper and the number of marks it is worth, and let a committee of any of the learned societies of London have access to all the papers if they desire it. Again, let the matriculation be passed at any period of a man's life, and let the examination follow, irrespective of how he acquired his knowledge. In fact, let the M.D. be the test of a certain amount of knowledge, and not of holding "such views as are likely to satisfy examiners".

The London University is under the control of Government, and was founded by the Liberals, and is the most illiberal of all our universities. Can we not make a push to bring it within the spirit of the age, and make knowledge, not "views", nor yet crutches, the source of honour? Why should there not be one standard for matriculation at all our universities? Is it not true, now as ever, that "they manage these things better in France"?—Your very obedient servant,  
M.A. DUFFLIN, M.D. EDIN.

**P.S.**—Is it true that some of the London medical schools ignore their university, and prepare their pupils only for the College of Physicians?

**H. M.**—The fees for a complete medical education in Paris amount to 1272 francs, or about £53. A Paris degree does not at present entitle its possessor to practise in England.

#### CONJOINT BOARDS.

**SIR,**—On reading an account of a deputation from the Council of the University of London to the Duke of Westminster on Tuesday last, there is one thing which appears never to have entered the minds of Drs. Carpenter, Storrie, Sharpey, etc., in attacking the universities and corporations of Scotland and Ireland—viz., the present system of permitting quacks and unlicensed practitioners to prey much as they like upon the public. Now, before these self-constituted censors attack universities and colleges in the sister countries, which have so honourably carried out all the recommendations of the General Medical Council to raise medical education to its present high standing, they should never forget that there are matters of the greatest possible moment to be adjusted to the satisfaction of the public and profession alike; and it is not by abusing medical schools outside of England that good will result. Why is it only now discovered that we are in such a disgraceful condition that immediate legislation is demanded to overturn a system which has wrought such benefit to the entire community? It is certainly untrue to say that the licensing bodies of Scotland and Ireland have been negligent in their duties by sending forth to the world practitioners ignorant and badly educated. There is not one college in the three kingdoms but has its honour and credit staked in the condition of its examinations; and to say that, unless there is a combination of all the bodies to participate in the examinations, no properly qualified practitioner can emerge from beneath college portals, is simply to urge an impracticable and unjust scheme. Medical examinations are so carried out now-a-days, that no one who does not show a fair knowledge of all the branches of his profession has the shadow of a chance of gaining a certificate to practise under the Medical Acts. It is not to be expected of a candidate that he should possess the erudition and skill of a professor of the numerous branches in medicine and surgery.

If legislation be necessary to raise the standard of medical education, let the Government adopt the system in vogue in Germany—viz., to look upon all qualifications from universities and colleges as merely a signification that the holder of such has complied with the regulations and prepared himself for undergoing the state examination—an ordeal by no means easy. Till some such plan is the law of the land, there can be no true check upon the host of quacks and pretenders to medical knowledge, who prey upon the public with the greatest audacity, and without hindrance from these in authority.—I am, etc.,  
Edinburgh, May 23rd, 1878. J. H. COCHRANE, L.R.C.P., L.R.C.S. ED.

#### BONDS WITH ASSISTANTS.

**SIR,**—If any of your readers would oblige me by answering the following questions respecting bonds with assistants, it would be of general interest. What are the precise terms or items in a bond between master and assistant, in which the former binds the latter not to practise after he has ceased employing him? Does it require a lawyer to make the bond every time an assistant is changed? If so, what is the usual charge?—I am, etc.,  
Medicus.

## LAC NOIR, SWITZERLAND.

SIR,—Allow me to recommend to the notice of your readers an establishment and health-resort in a mountainous part of Switzerland, situated in the vicinity of Fribourg, and of easy access from that town, being a three hours' drive by omnibus or carriage. It offers at once the attractions of a country residence, without being so far from town life as to cause inconvenience. There is a good hotel, with accommodation for eighty or ninety persons. The charges are among the most moderate to be met with in Switzerland, ranging from six to nine francs a day. Telegraphic communication with Fribourg and Berne has been recently established. A post leaves every morning for Fribourg at 6 A.M., courier returning with the mail at 5 P.M. The lake from which the place takes its name is of great depth, and as clear as crystal, abounding in fish of great variety and delicacy. Sailing and rowing boats are provided free of expense to all visitors, while numerous excursions can be undertaken among the surrounding mountains, where lovely wild flowers, as the alpenrose or rhododendron, gentian, etc., are to be met with. A sulphur-spring at the back of the hotel has been found of great benefit to invalids, and the master of the establishment has accordingly caused baths to be constructed for the benefit of visitors suffering from any complaint likely to be remedied by the sulphur waters. A few hours' climbing brings the tourist to the magnificent panorama of the overland range.

As a cool retreat during the hot summer months, I consider the place unequalled; and to those suffering from chronic chest-affections, general debility after illness, anæmia, or derangement of the digestive organs, it can be strongly recommended. The air is rendered quite fragrant by the surrounding pine forests, similar to those of Bournemouth, and the soil is almost equally dry. By those who are robust, bathing can be indulged in, as the proprietor has erected two bathing-houses at the edge of the lake, the water of which is at all times of the clearest crystal, reflecting, as in a mirror, the surrounding heights, covered at one point with magnificent pines, in other places clothed with the richest pasture. I may add, the elevation of Lac Noir, being three thousand five hundred feet above the level of the sea, ensures even at the height of summer a cool atmosphere, free from fog; and even after heavy rains the ground rapidly dries, a desideratum not always met with in similar altitudes.—I am, etc.,  
C. V. CAY, M.D.,  
Surgeon-Major Coldstream Guards.

A MEDICAL OFFICER OF HEALTH (TORQUAY) asks: What is the best material with which to stuff the beds of a fever hospital, and which is the best dry heat disinfectant?

## THE BRUSSELS DEGREE.

WILL C. B. G. kindly send his name and address, which have been mislaid? A member of the profession is desirous of communicating with him respecting the subject of his letter in the JOURNAL of April 6th.

F. FRYER (Dewsbury).—The pamphlet on *Provident Dispensaries*, by Sir Charles Trevelyan, together with a model set of by-laws for such dispensaries, may be procured from the Secretary of the Charity Organisation Society, Buckingham Street, Adelphi, London.

## ON THE TREATMENT OF PUERPERAL HYPERTHERMIA BY COLD; AND ON HOSPITALISM.

SIR,—Will you kindly allow me to make one or two observations on Dr. Wiltshire's very interesting article "On the Treatment of Puerperal Hyperthermia by Cold," which appeared in your JOURNAL on the 18th instant? The refreshing, grateful sensation from the action of cool air on the skin, and from the evaporation of water or eau de Cologne on the palms of the hands and the soles of the feet, in all cases of fever, is acknowledged by every one; and the dry cold method, by which the patient is conveniently packed round with closed vessels filled with pieces of ice, in lieu of the wet applications and the cold bath, is, as Dr. Wiltshire says, of much importance in the treatment of hyperthermia in cases where the patient is much exhausted and cannot be moved.

The abstraction of heat from the body by the application of cold appears to me to be merely a physical action, and if not continued long enough there may be great reaction; the application must therefore be renewed frequently, and finally, when the temperature of the body is reduced, this must evidently be in some measure at the expense of the patient's vitality. We submit that, by securing a good atmosphere for our patient, we obtain that physiological animal heat which assuredly is the best means of overcoming the morbid action. This will not deprive us of the grateful action of cold by local applications; the vital powers being well supported, the recovery will be more prompt and sure.

In puerperal cases, there is an immense amount of putrescible animal matter carried into the atmosphere which surrounds the patient, and which accumulates rapidly in the furniture, in the porous walls, ceilings, and floors, if it be not continuously swept away and purified by the admission of fresh air. Dr. Wiltshire clearly shows us this when he says that the patient who died would have recovered if she could have been removed from the hospital, "for again and again her temperature fell to normal, or nearly to it, and she appeared to be on the verge of convalescence; she seemed, however, to get fresh doses of poison, and relapsed accordingly." Why should this be? Cannot the atmosphere of the hospital be kept pure when we know whence the poison comes? If the walls and ceilings be covered with an impermeable coating, the oak-floors waxed and well rubbed, and if the quantity of air necessary to carry off the impure atmosphere be constantly admitted, with the prescribed habit of order and cleanliness required in hospitals, we shall no longer have to contend with those fearful puerperal and other nosocomial diseases. The hospitals will then be in a fit state to receive cases of this nature without any fear of contagion, for these diseases are transmissible there only where they may have originated.

As hospital diseases are preventable, and as the salubrity of the hospital is completely under our control, do you not think, sir, that these diseases should be prevented? and when death occurs from the neglect of proper hygienic measures, do you not consider that such a death is a case for a coroner's inquest, and that the board of governors of the hospital should be made responsible for it?—I am, sir, yours faithfully,  
CHARLES SHRIMPTON, M.D.

5, Whitehall, May 22nd, 1878.

## ANÆSTHETICS IN DENTAL SURGERY.

SIR, I have read with much interest your report of, and remarks on, "Deaths from Anæsthetics" in the BRITISH MEDICAL JOURNAL of May 11th and 18th, and hope some discussion may arise therefrom. Whilst strongly deprecating the want of caution too frequently exhibited when the use of an anæsthetic is demanded, I think that there are some anomalies in the practice of dental surgery where a more perfect anæsthetic than a peroxide of nitrogen is requisite; and I advance this after more than twenty years' experience. In instance, a patient comes to us with a quantity of loose, stringy and broken-down teeth, setting up alveolar abscesses,

frequently scattered in different parts of the mouth, and not lying contiguous to each other. The individual has submitted to a great deal of suffering from a dread of the cold steel, which many an unfortunate mortal in the same condition frequently exhibits. The patient being exhausted by local pain, as well as by the concomitant ills which such a condition is sure to set up, surely here is a case demanding an anæsthetic quite as legitimately as many other operations for which chloroform or ether would, without hesitation, be used, if the patient, on examination, proved a fit subject. If in this case we used peroxide of nitrogen, the patient would have recovered consciousness long before the completion of what was requisite, for the state of anæsthesia produced is so transient that under the most favourable circumstances we can rarely remove more than a couple of molar teeth while it lasts; and if there be any complication, frequently not one. Here, surely, it would be justifiable to choose one of the anæsthetics you would so inexorably banish from the dentist's consulting-room, and complete the work, rather than condemn the patient to return home until he or she had got over the administration of the gas, to return another day for a repetition of the operations.

I think we are in no case justified in administering any anæsthetic without a thorough examination as to the physical condition of our patient, to ascertain if any symptoms exist that would contraindicate its use; and personally, under no conditions whatever will I administer any anæsthetic without the presence of a medical man, for not even peroxide of nitrogen is without its risks. Two cases have proved fatal to the patient; and I have heard of cases where artificial respiration had to be resorted to to recover the patient—a state of affairs I would rather not have to face unassisted; and who is to say when it may recur?—Hoping this letter may provoke discussion, believe me, yours faithfully,  
J. T. BROWNE-MASON.

6, Southernhay, Exeter, May 25th, 1878.

DR. EDWARD T. WILSON, Westall, Cheltenham, will feel greatly obliged to any of our readers who will kindly supply him with reports of hospitals for infectious disease, or any information respecting the practical working of such institutions.

## MEDICAL ADVERTISEMENTS.

SIR,—The following is a copy of an advertisement put into a local paper by a young surgeon commencing practice in this town, a short distance from, and in opposition to, his old master.

"W. Parker Tait, Surgeon, 5, Stanley Square, Staleybridge, has opened his Surgery at the above address. Messages left will be attended to."

As to the presence or absence of medical etiquette in the two acts, I will leave your readers to judge.

I forward you with this letter a paper containing the advertisement referred to, and beg to remain, respectfully yours,  
HERBERT A. BRIDGMAN.  
53, Grosvenor Square, Staleybridge, June 1st, 1878.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelson Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

## COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. George Johnson, London; Dr. J. Marion Sims, Paris; Mr. T. Spencer Wells, London; Dr. R. Greenhalgh, London; Dr. Riggrope Atkins, Waterford; Dr. W. A. Sturge, London; Surgeon-General C. R. Francis, Sutton; Dr. J. B. Bradbury, Cambridge; Surgeon-Major J. H. Porter, Netley; Dr. George Harley, London; Dr. F. A. Mahomed, London; Mr. William Adams, London; Dr. Farquharson, London; Dr. J. W. Moore, Dublin; Dr. J. Milner Fothergill, London; Dr. J. Bell, Edinburgh; Dr. Edis, London; Dr. Raddcliffe, London; Dr. A. S. Taylor, London; Dr. D. Foulis, Glasgow; Mr. G. Eastes, London; Mr. R. S. Fowler, Bath; Dr. F. J. Brown, Rochester; Dr. William Squire, London; Mr. Richard Barwell, London; The Secretary of the Royal Medical and Chirurgical Society; Mr. Richard Davy, London; The Secretary of Apothecaries' Hall; M.D.Ed.; Mr. Balmanno Squire, London; The Registrar-General of England; Mr. T. M. Stone, London; Dr. C. Theodore Williams, London; Mr. Wanklyn, London; The Registrar-General of Ireland; W.; M.R.C.S.Eng.; Dr. W. Fairlie Clarke, Southborough; Dr. Clifford Allbutt, Leeds; Mr. J. M. Williams, Rhyl; Dr. Alfred Renshaw, Sale; Mr. J. G. Langley, London; Dr. Annington, Cambridge; Dr. Wardell, Tunbridge Wells; Dr. E. Markham Skerritt, Bristol; Dr. Duke, London; Mr. Allen Fielding, Canterbury; Dr. Levinge, Bristol; Dr. Bowles, Folkestone; Mr. J. M. Bennett, Liverpool; Lord Cairns, London; Dr. Thin, London; Mr. A. H. Mason, London; Dr. Collie, Homerton; Dr. T. F. Chavasse, Birmingham; Mr. Bridgman, Staleybridge; Dr. Waters, Chester; The Secretary of St. Thomas's Hospital; M.D.; Dr. C. Murchison, London; Dr. Birnbaum, Swallow; The Secretary of the Epidemiological Society; Mr. Samuel Benton, London; The Rev. Dr. Haughton, Dublin; Dr. Cameron, M.P., London; Mr. Christopher Heath, London; Dr. Tripe, London; Dr. Trollope, Hastings; Dr. Haddon, Bandon; Mr. F. Fryer, Dewsbury; Mr. W. Moxon, Northampton; Mr. C. H. Hutchinson, Scarborough; Dr. Robinson, Dublin; Mr. A. H. Benson, Dublin; Dr. Alfred Meadows, London; Mr. G. E. Corrie Jackson, London; Mr. W. H. Wright, Dublin; X.; Our Edinburgh Correspondent; Dr. Wilson, Cheltenham; Our Dublin Correspondent; Messrs. H. K. Edge and Co., London; Dr. R. T. Cooper, London; Mr. A. Corrie, London; Mr. G. H. Fosbrooke, Bedford; A. H. T. C., Liverpool; Mr. Tomes, London; Mr. C. Williams, Norwich; Mr. R. Pounsett, Lindfield; Dr. C. J. Roy, Strassburg; Mr. W. H. Michael, London; Dr. Joseph Rogers, London; Anti-Humbag; etc.

## LECTURES

ON THE

DIAGNOSIS AND SURGICAL TREATMENT  
OF ABDOMINAL TUMOURS.*Delivered at the Royal College of Surgeons of England.*

BY

T. SPENCER WELLS, F.R.C.S.

Professor of Surgery and Pathology in the College; and Consulting Surgeon to the Samaritan Hospital.

## LECTURE I—June 10th, 1878.

*Mode of Examining Patients with Abdominal Tumours; External, Internal, and Combined Examination; Form of Note-Book for Recording Cases; Collections of Fluid in the Abdominal Cavity and in the Cyst; Ovarian, Renal, and Hydatid Cysts; Illustrative Specimens from Museum; Chemical Examination of Fluids removed by Tapping.*

MR. PRESIDENT AND GENTLEMEN,—The honourable position of Professor of Surgery and Pathology, which, by the kindness of my colleagues on the Council, I hold this year, has been filled in past times by some of the greatest men in our profession. Abernethy, Cooper, Bell, Green, Lawrence, Brodie, Guthrie, and Fergusson are among those who have passed away. Of past professors still happily amongst us, and giving encouragement by their presence, some have published their lectures as actually delivered here; and I have only to mention Paget's *Surgical Pathology*, Hilton's *Rest and Pain*, Clark's *Surgical Diagnosis*, Hancock's *Surgery of the Foot*, and Hewett's *Injuries of the Head*, without doing more than allude to recent lectures which have appeared in the medical journals soon after delivery, to prove that the able men who have preceded me in this professorship have worked so well that, while they afford the stimulus of a bright example, they also make me painfully conscious of my inability to tread worthily in their footsteps. It would be presumptuous in me to attempt to rival them. All that I can do is to bring before you in the plainest manner the results of twenty years' exceptionally large observation and practice in a department of surgery which, until lately, has not received much attention here; and in endeavouring to tell what I have learned about the diagnosis and surgical treatment of abdominal tumours, how I have learned it, the lessons that I have been taught by mistakes and failures, the satisfaction which has attended increasing success, I may be of use in directing the thoughts and studies of some of the men who will practise surgery in years to come, and thus help to fulfil the great object for which this College exists, the lessening of suffering and the saving of life.

In the printed summary which has been circulated, it may be seen that I have arranged in an order which will allow me to present to you many valuable specimens from the museum, abundant material for the six hours allotted to me, and I will now ask you to imagine that we are about to examine a patient who is supposed to have an abdominal tumour. I need hardly say it is desirable to pursue in an examination of this kind a somewhat uniform plan or method; and, after a good many trials, I arrived at a mode of arranging the various questions and answers in a form, which, after a variety of changes, have at last arrived at this form of Note-Book, which I will send round, and which is published for general use by Messrs. Churchill. You will find in each book, arranged in pages, a series of questions which may be put in order to a patient when she presents herself in one's own consulting-room, or when called to see her at her lodgings; and spaces are left for the answers that may be given.

On the first page, one simply enters the date of the visit, the name and age of the patient, and the residence, which should be filled up in considerable detail and exactitude, because years afterwards, if it be imperfectly done, there is a good deal of trouble in finding out what has become of a patient. It is only those who have tried to do this who know how difficult it is to trace a case from its commencement to its close. Following the residence, comes a note where the patient was born and formerly resided, which also affords some assistance towards

understanding the history of the patient. When I was in America, at Professor Gross's Clinique in Philadelphia, he invited me to make some clinical observations upon a woman, and, to my surprise, she was a black woman. Dr. Atlee, who was present, whispered to me: "It is a very rare thing to see ovarian disease in a black woman." That at once put me on my guard, and really the tumour did turn out to be not ovarian, but a fibroid tumour of the uterus, which Dr. Atlee afterwards told me was extremely common amongst negroes. Dr. Knox told me it was rare to find ovarian disease amongst what he called cross-breeds; that the Celt and the Saxon are liable to them, but he had never seen one in what he called a cross-breed. That is a question I have never been able to examine into very closely, because it is so difficult to find exactly what may be a real true Celt or Saxon in these days, or what Dr. Knox would call a cross-breed. But these points are of some interest; and, after examining a great many patients, and getting a number of these books together, one can by annotation, examine how far statements of this sort are true or not.

Then one comes next to the question as to whether the patient is married, single, or a widow: if married, how long; if she have children, how many, and what their ages are, and whether she has suckled them. I have left out "lactation" in my note-book; but it is rather an important point, and will be inserted in any future edition. Then I have a question as to the number of abortions, and the name of the usual medical attendant. These are merely a few questions which serve to commence an acquaintance with the patient, and afford information of importance. On the next page, you will see a number of notes as to the general appearance of the patient. I am speaking rather of the patient herself than of her abdomen—the general aspect which she presents—what is her expression, whether cheerful or anxious, and what her apparent age as related to her real age. That is a matter of some consequence, because I think most of us would say a woman who looked considerably older than she stated herself to be, would be a less favourable subject for an operation than a woman whose apparent age was less than she stated, who looked younger than she really was. Then, with regard to the height or build of the patient—whether she is a strong well-built person, or a person below par in that respect. Then, as to complexion—whether she is fair or dark, pale or florid. This, we shall see, has some bearing on the diagnosis between ovarian and uterine tumours. Women with uterine tumours have a physiognomy which is more or less marked, one of the points being a good deal of coloration of face; whereas ovarian patients are more commonly pallid. Then we note something as to corpulence or emaciation, and muscular development. Then we regard the amount of hair developed on the surface of the body. Some persons have supposed that patients who have a large growth of hair are more subject to cysts like ovarian cysts, and so on, but I really have not been able to note that; for I have seen patients with a great deal of hair, and also with very little hair, both suffering from the same complaint. We next note the temperature of the skin and extremities; perspiration—whether it occurs during rest or under exertion, or whether there is any peculiar odour or acidity about it. Then we notice the presence of any glandular swellings, or eruptions, or ulcers, or old cicatrices—whether there are any varicose veins, particularly about the legs, or œdema of legs or feet; the condition of the areola round the nipple, particularly when there is any doubt as to pregnancy, and any special alterations in the hair or nails. These are all points which are seen at once, and, when one is in the habit of going over these headings regularly, the first view of a patient enables one to see directly what the case is likely to be.

Having done that, one turns to the next page, and proceeds from the general examination to an examination of the abdomen; and this may often be done quite as well in a surgeon's consulting-room as with the patient in bed. Of course, in some cases it is more convenient to examine the patient in bed, where the chest and abdomen can be thoroughly examined; but it is quite easy, in one's consulting-room, to remove the dress of a patient sufficiently, and to cover the limbs and lower part of the body with a shawl or towel, in such a way that the examination can be quite satisfactorily made without the least indecency.

Then, I would say, the first thing is to notice what one sees. We see at once whether there is visible enlargement of the abdomen or not, and if this enlargement is general or local; if one side of the abdomen is enlarged or if both sides are enlarged. One notices also the amount of subcutaneous fat, and, of course, if the patient is unusually thin and the abdomen retracted. The umbilicus is at once seen, whether it is concave or convex; and one also notices if there be any discharge there. Dilated veins at once come into view. One notes their size and the course they run, and sees any lineæ albicantes which may have remained after pregnancy or any other distension of the abdomen, and

one sees occasionally that these may be oedematous. These linear albicantes were formerly called varicose lymphatics, but there is no ground for that. Then, one frequently notices, in pregnant women, and most markedly in those pregnant for the first time, a brown mark running down the centre of the abdomen, which is a very common sign of pregnancy; and any hernial protrusion is also seen.

From seeing one proceeds to feeling; and we notice, by passing the hand over the surface, what its heat may be, and whether any unusual heat is confined to one side or is symmetrical; and one also feels if the abdominal wall is tense or flaccid; if there are any knots about it, or if it is oedematous. Then we also notice if there is any crepitation—if, on pressing the hand over any swelling, there is a feeling of friction beneath the hand; and also whether there are any movements of gas, or of mixtures of gas and fluid, which may gurgle. And then, with the two hands, one also may feel if there is that sensation of fluid, or wave of fluid, which is so well known as fluctuation; and one may be able also to appreciate whether the wave is fluid, or merely a sort of bag of jelly which moves about with the sensation which has been called "elastic impulse". Pulsation may also be felt, or a thrill; and one can estimate, with a little care, the seat of pulsation—whether it follows the course of the aorta, or whether it is felt elsewhere, and whether it may be simply the impulse transmitted from the heart's action downwards. Then we should also notice how these movements are affected by deep inspiration and full expiration, and also by sudden pressure.

Next, as assisting inspection, we come to measurement; and there is, on the third page, a diagram, which we are in the habit of using, in which five different measurements are marked down: first, the girth at the umbilical level, then a measurement from the lower end of the sternum to the umbilicus, and from that to the pubes, and then from the right and left anterior superior spine of the ilium to the umbilicus. By these five different measurements, and also by marking out on the diagram the outline of any tumour that may be felt, we obtain a very accurate record of any swelling or tumour which is existing at the time of the first examination of the patient.

Then, from seeing, feeling, and measuring, we proceed to listen; and are able to mark out pretty distinctly what are the outlines of the liver or spleen, and what parts are dull, and which are resonant on percussion, and their exact seat and limits. We observe any unusual dullness over the liver, and whether it extends too far downwards, or whether the heart is pushed out of its place, or whether there is any definable tumour of any part of the abdominal cavity, by the dull sound which solid tumours give on percussion, as distinguished from the resonance of the intestines. The effect of altered position would also be noticed: turning the patient from side to side, raising the shoulders or hips, seeing what effect that has, and watching also the effect of respiration upon any dullness, and also seeing whether, on repulsion, there is anything like hydatid fremitus developed by the alternate impulse of the two hands. (A diagram showing the position of the viscera was referred to.)

Proceeding to observe the sounds heard on auscultation, one may note where any gurgling sound of the intestine and any friction sound is audible, where the sound of the aorta may be heard, whether there is any vascular murmur, or any foetal heart-sounds, and whether there is any sound accompanying succussion or fluctuation. All these things are frequently heard, and occasionally, where there is a mixture of air with fluid, one can hear the sound so well known by auscultators as "metallic tinkling"—air bubbling through fluid. What assistance the microphone may give us, I hardly know yet; but it is very probable that the foetal heart-sounds may be heard much more distinctly than they are by an ordinary stethoscope.

All this examination may or may not lead to the detection of a tumour; but we will suppose a tumour has been discovered; and then we have to determine whether there is only one tumour or more than one; supposing there to be more than one, if they are united or separate; whether they can be moved one upon another; and we mark on the diagram the exact position and outline of each of them, and note in what position of the patient they are best seen and felt. Then, one would also notice whether there is any connection with any of the abdominal organs—with the liver, the kidney, the uterus, or the spleen. This would at once become apparent by the position of the tumour; and one would notice also the surface of the tumour, whether smooth, or irregular and knotty; what its consistence was, hard or tense, soft or boggy, or whether any fluctuation which could be detected in it was uniform or limited, deep or superficial, and whether the superficial fluctuation was over the surface or only felt upon deep pressure of the tumour.

With regard to mobility, one would note to what extent the tumour may be moved upwards or downwards, or from side to side; whether the abdominal walls moved over it or not, or whether they were con-

nected with the tumour, and whether any movable portions of the tumour are more or less independent of its general mass; whether one tumour may be moved independently of others, and occasionally, when the abdominal wall is flaccid, one is able to make some kind of guess as to the probable weight of the tumour. It may be advisable also to ascertain what is the effect of meals, of vomiting, of purging, or of catheterism on any tumour that has been detected.

Having examined the abdomen in this way, one proceeds to the examination of the pelvis. In a man, of course, this is not so frequently necessary; but, in examining a woman, it is always necessary to ascertain whether an abdominal tumour is connected with any of the organs of the pelvis. One has to ascertain the position and size of the uterus, and the connections of any tumour with it; and all this can be done before any questions need be asked of the patient beyond a few preliminary inquiries. The examination by the vagina—feeling the uterus, feeling any tumour between the uterus and the rectum, or any tumour that interferes with the movement of the uterus, or presses it downwards, or draws it upwards, or presses it to one side—is an examination upon which I need not enlarge now; but there are one or two points on which I wish to say a few words. In the first place, examining by the vagina in a young unmarried woman with a perfect hymen is often quite needless. One can ascertain all that is necessary by rectal examination. With one finger in the rectum of a woman, one can feel very well the posterior surface of the uterus, and can make out pretty clearly whether there is anything below the brim of the pelvis without examining by the vagina at all. In married women, or in women where it is necessary to make a vaginal examination, the simple vaginal examination only does not, as a rule, afford very much information. You can tell whether the neck of the uterus is in its normal position, whether it is enlarged or whether it is small, whether it is hard or soft, or with any apparent growth from it; but one can get a great deal more information in cases of suspected tumour by combining the internal and external examination, putting one hand on the abdomen, and passing the finger of the other hand into the vagina, feeling the uterus; and then, moving about any abdominal tumour that there may be, one is able to tell pretty clearly whether the uterus is closely connected with any tumour, whether the tumour moves independently of the uterus, or, supposing it does move with the uterus more or less, whether that movement is transmitted or one closely associated with it; whether the uterus itself is enlarged or moves with the tumour, or whether any movement that affects the cervix of the uterus is simply communicated to it.

One may go further than this in combining internal and external examination. By passing a thumb into the rectum and a forefinger into the vagina, one can feel very clearly what is contained in Douglas's pouch; and, on the other hand, putting a thumb of the right hand into the vagina and the forefinger into the rectum, one can feel very distinctly a considerable part of the uterus even to the fundus, and so get a notion of its size and form, and that of anything attached to its exterior either in front, behind, or at the fundus. Supposing this fold is depressed by fluid, or that the small intestines come down lower than usual, on pressing the thumb and the finger together, one gets very clear and distinct information of anything there may be between the uterus and the rectum, or the posterior wall of the vagina and the rectum.

Simon of Heidelberg laid great stress on the combined examination of the bladder and the uterus after dilatation of the urethra, believing that this was not only useful in completing examination of the bladder itself, but also for examining growths in the pouch between the bladder and the uterus. If you have anything formed between the front of the uterus and the top of the bladder, if you dilate the urethra well, you are able to make a very accurate examination, not only of the state of the bladder, but also of anything there may be between the bladder and the uterus. I cannot say I have myself ever found this very necessary, or have got much information from it.

In some cases, where there may be a doubt as to the state of the uterus, and where the cervix is small and one is doubtful what may be its condition, then, if the sponge-tent be introduced, left for a few hours, and the cervix well dilated, one is afterwards able to make more complete and accurate examination. Or, by a combined examination between the abdominal wall and the rectum, one is occasionally able to ascertain that there is a congenital absence of the uterus; for one's finger in the rectum meets the finger depressing the abdominal wall, and that may be sometimes checked also by examination of the bladder.

I have lately added a good deal to our knowledge of this combined examination, by showing what one gains by pulling the neck of the uterus downwards after fixing it by a long hooked forceps. I have used Sims's hook, as less likely to do harm; and, by drawing the

cervix downwards, one is often very able to ascertain whether the uterus forms part of a tumour or growth, or whether it is separated from it. Combining this pulling down of the uterus with a hand on the abdominal wall and a finger in the rectum, one can get a very accurate idea of the contents of the pelvis; or, entrusting the uterus pulled down by a hook to a careful assistant, who will not pull too violently, with one finger of the surgeon's hand in the rectum and the other hand depressing the abdominal wall, one obtains a very complete idea of what there may be below the brim of the pelvis. Of course, I am supposing that there is not any extraordinary amount of fat on the abdominal wall, or any peculiar rigidity in the vagina. In this way, one is able to recognise any flexions of the uterus, and may be able to replace them without the use of the sound. The examinations may be carried out sometimes with the patient on her back, sometimes on her side; and sometimes one observation is checked by the other, examining first in one position and then in the other; and occasionally, though very rarely, it is necessary to try the knee-and-elbow position, raising the pelvis and lowering the chest. In this position, a heavy tumour falls upwards and forwards, and sometimes a tumour which is low down, and giving great trouble by its pressure on the bladder or the rectum, may, by the mere position of the patient on her elbows and knees, be pressed out of the pelvis, pushed into the abdomen, and in this way great relief is given.

Simon of Heidelberg laid great stress upon the fact that, when a patient is deeply narcotised by chloroform, the whole hand of the surgeon may be passed into the rectum. He showed this to me at Heidelberg one day. A patient was put deeply under the influence of chloroform, and, without much difficulty, I put my whole hand into the rectum and passed it upwards, so that, under Simon's direction, I could quite distinctly feel the left kidney. There was no doubt about it. I got my hand well up into the descending colon and felt the kidney very distinctly. In some two or three cases of very doubtful diagnosis of tumours in women, I have done this in England; but I really cannot say I have gained more information by it than I could gain by the finger in the vagina or rectum, combined with pressure upon the abdominal wall.

All this knowledge one has gained for one's self without any questioning of the patient at all; simply by what one has been able to see, and feel, and hear. From that we must come to questioning. One is obliged to get from the patient some account of the state of her digestive organs and nervous system; the state of her respiratory organs and blood-circulation, all of which is noted in succeeding pages of the note-book. Following the examination of the pelvis, one comes to questions as to the state of the catamenia; when they commenced; when they ceased, if they have ceased, in an old woman; and any history of sudden suppression of catamenia from cold or any other cause; if there be any history of excess or deficiency, or any leucorrhoeal discharges, or discharges of any other kind. A very few questions enable one to fill up this page. The state of the urinary organs requires a little more time, because the urine has to be examined afterwards, unless the patient has previously sent a specimen; and then one gets the ordinary information about the colour and odour of the urine; its specific gravity, and what it contains. Then one comes to the history of the disease for which she applies for relief, and one learns something about any hereditary influence and the fecundity of the females, and the general duration of life in the family; her mode of life, any moral causes, and any previous diseases or accidents: these all require some slight note.

With regard to the early symptoms of the present illness, one likes to know something about the first signs: what was the first departure from good health; whether there has been pain or tenderness, particularly in the groin or the pubic region; any sense of fullness in the vagina, or bearing down of the uterus; any pressure on the bladder; any pain, numbness, or weakness in the thighs or legs; whether there is any constipation; what the state of the breasts was; whether she suffers from much nausea; whether the symptoms were aggravated at the monthly periods; and then as to when the tumour was discovered. Whether she noticed it for herself, or whether, as is likely, it was discovered by some medical man; then the rate at which it enlarged, whether rapidly or slowly, or whether there was any regularity in its enlargement; and particularly whether the increase or diminution was associated in any way with the monthly periods. Women with uterine tumours will frequently tell you that they are distinctly larger before the periods and smaller afterwards; and this helps us a great deal in the diagnosis between uterine tumours and tumours that are not uterine. Then as to movements felt in it, particularly with regard to pregnancy; and then a note of any early treatment often becomes interesting.

Proceeding from the early history of the case to the progressive

symptoms, a note is made of any changes one is told of in the situation of the tumour, and you are very frequently told some odd stories about it. I do not think there is much confidence to be placed in what patients tell you about these things; but still, occasionally, some history of particular changes in situation becomes of importance afterwards.

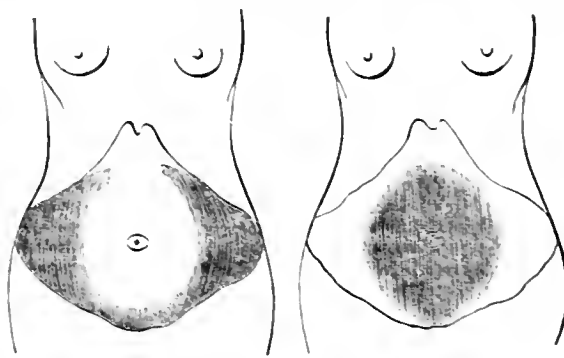

Then with regard to the aggravation of the early symptoms: any increasing difficulty of breathing; any increasing distension of the abdomen or intestines; any history of febrile attacks; any inflammation of a cyst or peritonitis surrounding it; whether there have been successive attacks of peritonitis, and any proof of the presence of peritoneal fluid. Next, if there have been any discharge of any kind, either through the uterus, the vagina, the bladder, the bowel, or through the abdominal wall. All this would have considerable weight at times. And, then, whether there has been any history of a rupture spontaneously, or by a blow or fall. Frequently there will be this sort of history given—that the abdomen gradually became larger and larger, and, at last, the patient suddenly fell down, or got a blow; or that, without any reason at all, there was a sudden alteration in the shape of the abdomen; a sudden attack of acute pain, followed by a large discharge of fluid, either by the kidneys or by the bowel, and then the abdomen flattened down more or less. Then, supposing the patient had been tapped, one likes to get the date of the tapping, and, as far as one can, some report of the nature of the fluid removed, and its quantity.

With all this information, we really ought to be able, and generally are able, to arrive at the heading which follows on the eleventh page of the book—a diagnosis of what the tumour may be; whether the patient has a tumour; what it is; and, generally speaking, I think this can be done at the first visit of the patient. It is very seldom one has to put off a patient and say the case is so doubtful that, until one has examined the urine, or made a more complete examination of something or another, it is impossible to say what it is. That, no doubt, is occasionally necessary; but, as a rule, with the sort of examination I have been trying to describe, we are pretty well able, by the time that we arrive at this eleventh page of the note-book, to make a diagnosis which is fairly and reasonably accurate.

Before deciding as to the treatment, one is able, I think, to form some kind of estimate as to what the probable duration of life will be if the patient is left alone, or if she is simply treated medically, or by palliative methods. We do know what the duration of life is in patients who have abdominal tumours of a sufficient size to interfere with locomotion and respiration—we know it is not long—and we are able to make a kind of approximate guess at what it is likely to be in any particular case.

One can also form a pretty good idea of what the general treatment should be as to diet and mode of life, and medical treatment, if any is necessary, and is able to say what surgical treatment may possibly be required hereafter.

Now, I will suppose we have a patient who has a collection of fluid, either free in the abdominal cavity, or contained in some cyst.

These two diagrams represent the abdomen of a patient containing fluid. We will suppose the central dark shade to represent fluid, and that the rest of the surface is resonant on percussion. The part of the abdomen which contains the fluid is dull on percussion. In this other case, the dark shade shows dulness on percussion on both sides, the patient lying on her back; the centre is resonant on percussion, but the sides are dull. In the first case, the central part is dull on percussion, and the sides are quite clear. The inference would be at once

that, with intestines at the sides and the fluid in the centre, the woman lying on her back, the fluid must be enclosed in a cyst. On the other hand, here the intestines are floating, giving a clear sound on percussion, and the fluid gravitates to the most depending parts of the cavity, and you will see at once the fluid must be free; the intestines are floating about and the fluid is beneath. As a rule, I suppose, in nine cases out of ten, that would probably be the correct diagnosis. You would say here was a case of ascites, and here, where the intestines are pressed backwards and the fluid is in the centre, that will be encysted fluid; and, in a large number of cases, that will be certainly true. But there will be exceptions. There may be so much fluid in the peritoneal cavity that the intestines do not touch the front of the abdomen, or the intestines may be fastened backwards by adhesions; and fluid, which appears to be in front and is in front, is there, not because it is enclosed in a cyst, but because the intestines are held back. And, on the contrary, one may get a case where fluid is enclosed in the front by coils of intestine round it, and is circumscribed in that manner.

I have had a number of preparations brought down to show the way in which adhesions of different portions of the intestine to each other, and to the abdominal wall, may simulate cysts—may become false cysts. The fluid is encapsuled, not by a cyst, but by surrounding portions of intestine or omentum adhering to each other, or to some part of the abdominal wall. Those are our most puzzling cases in diagnosis at times. In the book on *Diseases of the Ovaries* which I published some years ago, there is rather a full account of all this, with which I need not trouble you now. I ought, however, to have mentioned that this fluid, when it is free, will move from side to side as the patient is moved. If she be turned on to her left side, the intestines go to the right; and when she is turned back again, the fluid sinks to the right side, and the intestines float up to the left. So when she is sitting up more or less, and her shoulders raised, the fluid sinks down towards the lower portion of the abdomen, leaving the upper free. If you put a pillow under the hips and lower the shoulders, it at once goes upwards towards the sternum. So, occasionally, one may be deceived by a cyst of moderate size sinking, if it be movable, from side to side as the patient is moved.

The alteration of the position of the patient makes considerably greater and more rapid changes in cases of ascites than in patients with ovarian cysts; the cyst moves about much more slowly than fluid. The superficial veins are more commonly enlarged in ascites than in ovarian dropsy, and, on measurement, the enlargement of the abdomen in ascites is more likely to be symmetrical than in the ovarian cyst; and then, on feeling the abdomen, you are more likely to get a flaccid abdominal wall in ascites, and a more tense wall in a cyst; and very often, in ascites, the greatest girth is at the umbilical level; whereas, in ovarian dropsy, it is sometimes considerably lower.

The way in which the fluctuation is felt is of some importance in ascites, the wave being a wave felt more immediately beneath the hand and not limited so distinctly by the cyst as in ovarian dropsy. Then, a very important question is the way in which the movements of respiration affect the dullness. Supposing one finds that, as the patient breathes deeply, resonance descends, it will often guide you correctly in a doubtful case by a careful examination as to how far the line of clearness on percussion varies or corresponds with the line of fluctuation. When you get distinct fluctuation beyond the limit of dullness—when you get evidently a wave of fluid moving about amongst the intestines—it is pretty certain that the fluid is free. However it may be limited, if one find that one has a distinct wave of fluctuation where one has a resonance indicating the presence of intestine, that must always certainly be free peritoneal fluid, and it is the same whether it is ascitic fluid or fluid escaped from a cyst. The fluid is free, with the intestines floating about. In the other case, you feel the wave of fluctuation limited exactly by the outline of the dullness. One can very seldom go wrong by carefully observing these two points.

I have said just now a doubt may arise where the quantity of fluid free in the peritoneal cavity is so very large that the front of the abdomen is pushed forward far beyond the reach of the intestines, the intestine cannot reach the surface of the abdominal wall, and so one has the fluid in front.

Another point of doubt and difficulty may arise from air having entered an ovarian cyst; for, as an ovarian cyst contains a certain amount of fluid, it may also contain gas, and either the fluid is decomposed after tapping, or there may have been some possible communication set up between the intestine and the interior of the cyst. Sir Thomas Watson records a case in which a patient had a cyst filled alternately with fluid and with air; when the fluid collected to a certain quantity, it seemed to open some valve like communication with the intestine, emptied itself, and became filled with air. As the fluid gradually reformed, the air was displaced, and the same series of

changes went through again. I have known a case in which air distinctly entered an ovarian cyst through the Fallopian tube—at least, we could find no other means of entrance; and, after death, it was found there was a large and distinct communication between the interior of a large ovarian cyst and the uterus through an enlarged Fallopian tube; there would have been, at any rate, no difficulty in air entering in that way.

Supposing doubt does arise as to whether fluid is free or not, one has always the resource of tapping; and a chemical and microscopical examination of the fluid that is removed will settle any doubt as to whether it is free peritoneal or ovarian fluid, or fluid of some other cyst. Years ago, before Scherer's test to distinguish albumen in its true form from the forms of albumen that chemists do not seem very accurately to determine, it was sometimes extremely doubtful to arrive easily at this determination. But Scherer showed that the albumen which, when coagulated by heat, is redissolved by acetic acid, is a very different albumen from true albumen. Paralbumen and metalbumen are forms that, when coagulated by heat, can be dissolved by acetic acid boiled. One takes a test-tube and boils the fluid, and the albumen is coagulated. You add some strong acetic acid, and give it a good boil, and shake it up, and if the albumen be true, the coagulum does not redissolve in the acetic acid. But supposing it to be paralbumen, then it either dissolves, or forms a whitish transparent fluid, or breaks up into a kind of jelly-like transparent mass, which is quite easily distinguishable from undissolved albumen coagulated by heat. This was supposed to be, for a long time, a pretty certain means of distinguishing between ascitic fluid and ovarian fluid. If the coagulated albumen were dissolved in acetic acid, it was said to be ovarian; and if it did not redissolve, it was said to be ascitic; and that was frequently right. Sometimes part would redissolve and part would not; and then the supposition was that it was a mixed fluid, some ovarian and some peritoneal, that an ovarian cyst had burst and some of the fluid was in the peritoneal cavity, a certain amount of fluid had been poured out, and there was a mixed fluid, which contained some true albumen and some paralbumen.

After a little further examination, one saw that there were exceptions to this rule. For instance, Dr. Schetelig of Hamburg once examined the fluid from a large renal cyst that I had emptied, and he found paralbumen and cholesterine, and no trace of urea, because the proper structure of the kidneys seemed to have been completely destroyed. He found in another patient that the fibrine found at the first tapping of the patient disappeared after another tapping, and he concluded that, at the first tapping, the fluid was removed from the peritoneal cavity, and, at the second tapping, from an ovarian cyst. It is quite possible, in tapping the abdomen, to remove a certain amount of peritoneal fluid and leave an ovarian cyst behind; and that, at another tapping, the ovarian cyst might be tapped and emptied, and the fluid escape.

After the chemical examination of the fluids removed, one has to resort to the microscope, and this we will consider at the commencement of the next lecture.

## NOTE ON THE MICROPHONE AND TELEPHONE IN AUSCULTATION.

By JOHN G. MCKENDRICK, M.D.,

Professor of Physiology in the University of Glasgow.

IN common with many others, I have been deeply interested in the recent remarkable inventions of the telephone, phonograph, and microphone, not only because these instruments promise to be useful, but also because I feel convinced that every advance in the obscure region of molecular physics is destined to have an important influence on our interpretation of many physiological phenomena. The results already obtained have given us a new conception of the delicacy of the organ of hearing and of the action of the membrana tympani, and it is interesting for the physiologist to note that the secret of success with the telephone and phonograph is to imitate as nearly as possible the conditions in which the living organ of hearing works.

The ingenious invention of Mr. Hughes, the microphone, has already been employed by Sir Henry Thompson for the detection of minute calculi in the bladder, and not a few are attempting to apply it to ordinary auscultation. During the past fortnight, I have been trying a number of experiments, the results of which may be of interest, and possibly they may suggest improved methods to others.

The arrangement of Mr. Hughes which I have used consists of two little pillars of gas-carbon, having between them a spindle-shaped piece of the same material free to move in sockets in the pillars. The wires

are attached to these pillars, and a weak battery (say one or two Daniell's) and two telephones are put in circuit.\* Such an arrangement, if carefully made and adjusted, is very sensitive; and, although the wings of imagination have carried some writers much too far as regards the possibilities of the instrument, still many of the results described may be obtained by anyone with little trouble.

To hear the cardiac sounds, the best arrangement I have devised is the following. The microphone is fixed on the membrane of one of Marey's tambours placed vertically, and connected by India-rubber tubing with the cardiograph, also of M. Marey.† Thus the sounds may be transmitted to a distant telephone. It is important to note, however, that their character is altered. They have a resemblance to the cardiac sounds, but they are different in *timbre*. This effect may be well observed by fixing the microphone to the key-board of a piano. The sounds heard in the distant telephone, when the piano is played gently, are sharp and tinkling, like the sounds produced by a musical box, and without the resonance of the ordinary sound of the instrument.

Respiratory sounds can also be heard. When the cardiograph is placed over the larynx, a whisper is transmitted quite distinctly.

So far as my experience goes at present, the combination of the microphone with the telephone does not reveal to the ear of the auscultator new sounds with which he was previously unacquainted; but it can effect the transmission of sound to a great distance. I can conceive it quite possible that even such feeble sounds as those produced by the heart and lungs might be transmitted for many miles and be correctly interpreted by an educated ear. There is a limit, however, even to the capabilities of the microphone. The intermediate piece of carbon must be free to move, and any vibration communicated through solids, liquids, or gases must have energy sufficient to move the carbon, or, at all events, to exert a strain upon it. If it be too weak to do either, then the telephone will make no response.

In these days of rapid progress, when facts are observed which startle even our most learned physicists, it is unwise to predict or conjecture; but the success hitherto obtained by others is a stimulus to every one to be up and doing.

## A CASE OF CHOREA TREATED BY THE SUBCUTANEOUS INJECTION OF CURARA.

By DAVID DRUMMOND, M.A., M.D.,

Physician to the Newcastle-upon-Tyne Infirmary, and Children's Hospital.

A BRIGHT intelligent girl of seven years was brought to the Children's Hospital as an out-patient about the middle of October last, two or three weeks after the commencement of an attack of chorea. She was seen at the out-patient room several times, and treated with bromide of potassium and arsenic, for general chorea. On November 12th, no abatement of the movements having taken place, she was admitted into the hospital about six weeks subsequent to the first appearance of the disease—a period when many children suffering from this affection begin to improve. I had been for some time anxious to try the effect of curara, or woorara, as some name the drug, in chorea; but, as a rule, as is well known, the attack only lasts about eight weeks, and, consequently, any experiment is apt to be fallacious; for what influence in the cure is ascribed to the therapeutic agent is most probably due to the *vis medicatrix nature*. But, in my present case, the disease was evidently not going to run its most usual course, therefore I resolved to try the poison, known for a long time to experimental physiologists, but only recently, I apprehend, to therapeutists; the fact that it has been recommended in hydrophobia having brought it prominently before the profession. With some trouble, I procured two drachms of a one per cent. solution—all the curara that was to be obtained in Newcastle. I commenced with five minims by the mouth, about one-twentieth of a grain of curara, three times a day, and in a few days increased this dose to one-tenth. This was continued for nearly a fortnight, but by this time no improvement had taken place, and all the curara was used. Whilst getting some more, I put her upon a mixture containing three grains of croton-chloral and ten grains of bromide of potassium for the dose, three times daily, which in a few days was doubled—that is, six grains of chloral and twenty of the bromide

three times daily. This treatment was continued for about ten days, but without effect, the choreic movements becoming more exaggerated. I now received a second supply of curara, as before, in solution, but this proved to be quite inert; even a quarter of a grain administered subcutaneously produced no physiological effects. I was about to give up trial as hopeless, when Mr. Bolam, chemist of this town, procured a few grains of the solid curara, and made a solution himself for me. It was now about fourteen weeks since the origin of the attack, and still there was no appearance of the choreic movements subsiding. Of this solution I commenced, on January 5th, injecting one-fortieth of a grain subcutaneously, only giving one injection in the day. On the 7th, I injected one-twentieth, next day one-tenth of a grain. On January 9th, one-eighth was used; she was by this time very much quieter; on January 11th, one-fifth, after which she was nearly steady. Two days afterwards, she got a quarter of a grain; after this, it seemed unnecessary to push the administration of so potent a poison any further.

It is very unfortunate that the specimens of curara vary in their strength and quality. Curara found in commerce is a brown-black resinous mass, soluble in water, but very slightly so in alcohol. The best solution for hypodermic injections is an aqueous one; it keeps well, and is, I imagine, less painful when used than either the alcoholic or the water and glycerine solution. One grain to twelve minims of water makes a good solution. The curara should be left in the water for forty-eight hours, and then filtered. The dose seems to be about one-quarter to one-half of a grain, though, owing to the uncertainty of the specimens, it is probably well to commence with a much smaller quantity. Of course, the *rationale* of the treatment of such affections as chorea, rabies, etc., by curara, depends upon the researches of Bernard, who, in 1844, discovered that the poison paralysed the ends of the motor nerves; and Schiff observed that the sensory nerves have to some extent their conducting power destroyed and reflex action much diminished, but that they are less affected, and after a longer interval, than the motor nerves. Death would eventually occur through paralysis of the respiratory centres, the circulation remaining almost normal. Sir Benjamin Brodie managed to save animals apparently killed by curara, by keeping up artificial respiration until the poison was eliminated.

Curara administered by the mouth seems to have very little effect, but should be injected under the skin; Ludimar Hermann explained this fact by showing that, when the kidneys were cut off from the circulation, physiological effects could be produced as well, though more slowly, through the stomach as by direct introduction into the circulation, the poison being very rapidly eliminated by the kidneys. A curious fact, and one which was well exemplified in my case, is that, even after the muscles are pretty well curarised, they react to electrical stimulus as perfectly as normal muscular tissue does. I compared the electrical reaction of the muscles of the forearm of the child, the subject of the present case, with that of a healthy child, and there was no difference. Bernard laid stress upon this fact, and showed that the muscles of a curarised frog, stimulated by the galvanic current, reacted perfectly; but such was not the case when the current was applied to the nerve itself, the muscle supplied by it refusing to react.

## CASE OF LITHOTOMY, IN WHICH AN ENLARGED MIDDLE LOBE OF THE PROSTATE GLAND WAS ACCIDENTALLY REMOVED.\*

By CHARLES WILLIAMS, F.R.C.S.,

Assistant-Surgeon to the Norfolk and Norwich Hospital.

THE specimen which I have the pleasure to exhibit to you represents an enlarged middle lobe of the prostate gland, accidentally removed from a gentleman on whom I performed the operation of lithotomy.

The patient was a tall thin man, aged 72, living about ten miles from Norwich. He had had symptoms of stone in the bladder for upwards of twelve months. A few months before I visited him, he had passed, on one or two occasions, a large quantity of blood in his urine. Of late, he had suffered much from the presence of the stone. He had been greatly disturbed during the night, and had become low-spirited. His urine was found to be quite healthy and free from albumen. His feet were in nowise oedematous; and he could eat freely. There was a loud systolic *bruit* heard over an extended area of the chest, giving rise to no inconvenience. Five years previously, he fractured the neck of his right thigh-bone; ankylosis of the hip-joint resulted from the injury, and he now walks with a perfectly straight and stiff, but shortened, limb.

On July 6th, with the assistance of Messrs. Morton, surgeons, of

\* Read before the Norfolk and Norwich Medico-Chirurgical Society.

\* I have not had the opportunity of seeing any microphone made by Mr. Hughes. The first one I saw was in the laboratory of Dr. Burdon Sanderson, about three weeks ago. Those I have worked with were made in my own laboratory.

† Marey's cardiograph is an instrument designed for transmitting cardiac movements to a recording tambour; but it is so suitable for auscultation, that I am surprised it has not been used for that purpose. By attaching an India-rubber tube of suitable length to it, one may auscultate with precision at a distance of many feet. The advantages are obvious.

Aylsham (under whose care this patient had been), I performed the usual lateral operation, and removed a single stone, of an oval flattened shape, weighing five drachms, of uric acid formation. An enlarged middle lobe of the prostate became engaged between the blades of the lithotomy-forceps, anterior to the hinge, and was unconsciously torn off and came away with the stone. There was free arterial hæmorrhage from a deeply seated vessel, which was without much difficulty seen and secured by ligature. A tube was placed in the wound.

On visiting the patient next day, I found him easy and comfortable. There had been no sickness; he had slept fairly well; pulse 64. The wound looked well; the urine was clear, and dropping freely from the tube and abundant in quantity. On the ninth day, he passed the whole of his urine through the penis, and the wound was healing rapidly. Three weeks later, I found him in excellent health, and the wound perfectly healed. He seldom found it necessary to micturate more than once during the night.

REMARKS.—This case presents some points of much interest.

1. The presence of a loud systolic *bruit* is not a pleasant sign in connection with the administration of chloroform, of which my patient inhaled from four to five drachms, and from which he suffered not the slightest inconvenience, either during the operation or subsequently.

2. The fracture of the neck of the right os femoris had resulted in ankylosis of the joint. The limb was immovably fixed in the straight position; therefore it could not be tied up in ordinary lithotomy fashion, but was held by an assistant in a straight direction over my left shoulder. This rendered the performance of the operation somewhat less easy than usual. The parts forming the perinæum were lax instead of being tense, and in order not to wound the rectum, which was large and flaccid, I passed my left forefinger into the bowel, and retained it until the point of the knife was lodged in the groove of the staff; and, by directing the edge of the knife very obliquely outwards, the rectum escaped injury—an event which, in all probability, would have occurred had not these precautions been adopted. If such an accident had happened, taking into account the age of the patient, I fear the termination of the case would have been unfavourable.

3. The removal of a large portion of the middle lobe of the prostate, though quite accidental, was attended with a happy result. The man was relieved of a trouble which, sooner or later, would have been a source of grievous annoyance to him.

I witnessed the same accident in a case operated on by Mr. Cadge. In the forceps, between the stone and the blades, there came away three masses, which were apparently fibrous outgrowths of the prostate, and which weighed one drachm two scruples. In two months, the wound had healed and the patient was strong and well. Mr. Cadge remarks: "It has happened to me twice before to remove small fibrous tumours of the prostate gland during the operation of lithotomy, and apparently without harm to the patient." (*Transactions of the London Pathological Society*, vol. xiii, 1862.) And he gives the experience of an expert modern lithotomist on this subject, who says: "It has occurred to me, eight or ten times, to bring away portions of the prostate and without noticeable injury to the patient. In more than one instance, it was the prominent third lobe which got between the handles, anterior to the hinge, and was torn off entire; and although I have never known unpleasant results to the patient, and that sometimes he has been benefited in after-life, by having got rid of an useless impediment to a natural function. I would not willingly that such an occurrence should happen, and I try to avoid it by turning the blade of the forceps to the lower angle of the wound as I leave the bladder; but when it does occur, I lay no account by it."

## THE POLYURIA OF GRANULAR KIDNEY.

By ROBERT SAUNDY, M.D. Edin., M.R.C.P. Lond.,  
Assistant-Physician to the General Hospital, Birmingham.

DR. GEORGE JOHNSON'S short paper, in the JOURNAL for May 25th, seems to me to call for some response from those who differ from him in the explanation of the facts to which he refers. While admitting the importance of the support Dr. Johnson derives from M. Charcot, in believing the changes in granular kidney to begin in the tubular epithelium, I do not consider M. Charcot's reasoning quite free from objection; and I hope, at some future time, to address myself to that part of the subject. For the present, I am concerned with the latter part of Dr. Johnson's article. Dr. Johnson says: "Dr. Ewald appears to have looked for hypertrophy of the arterioles in the pia mater alone, and therefore his observations are incomplete." "It is probable that the arterioles in other tissues, more especially in the skin, may have been sufficiently hypertrophied to explain the cardiac hypertrophy." Dr. Ewald, in common with most of Dr. Johnson's readers, did not imagine

that it was the part of his theory to exclude certain areas from the "stop-cock" function; but he shall speak for himself. He says: "I have restricted myself to this part (the pia mater of the pons) for many reasons: first, the vessels there are under the same conditions as all the other capillaries of the body which do not lie directly between the heart and the kidneys, so that the changes here found, as far as they are of an universal nature, must affect all the other vessels in the same degree. Secondly, because Gull and Sutton, and Johnson, have found the same changes in the vessels of the skin and intestines as they originally found in the cerebral vessels; so that if I could verify their results on one or the other side, in a limited region, the data would rightly hold for the whole vascular area. Finally, the vessels of the pia mater, as has been said, give the best preparations, and are besides more investigated and studied under pathological conditions, so that it is easier to distinguish the process in question from accidental or different pathological changes." (Virchow's *Archiv*, Band lxxi, Heft 4, page 458). In the second place, Ewald's argument, that "the absence of cardiac hypertrophy in amyloid and atheromatous thickening of the arterioles is against the vascular changes as causes of the heart-affection", must be taken as rather directed against the views of Gull and Sutton than against those of Dr. Johnson. Dr. Johnson goes on to say that "it has been suggested that the polyuria of granular kidney is the result of increased pressure in the Malpighian capillaries, consequent on obstruction in front". The existence of obstruction in front of the Malpighian tufts is proved by Thoma's researches. He found, by making careful coloured injections, that the fluid ran well into the tufts, but beyond them the capillary network had undergone destruction, and the efferent vessels were often obliterated (Virchow's *Archiv*, Band lxxi, Heft 3 and 4). Dr. Johnson says: "Increased pressure on the Malpighian capillaries would cause, not a copious secretion of urine, but an abundant transudation of albumen"; this is scarcely a fair assertion, as the transudation of albumen is the result of the high pressure being carried to an excessive degree. It is a generally accepted physiological fact, that the secretion of urinary water is in direct proportion to the pressure in the glomeruli. (Foster's *Text-Book of Physiology*, page 278, *et seq.*) He then enforces this statement by telling us that, "when, as a result of valvular disease of the heart, the return of venous blood from the kidney is impeded, the increased pressure on the Malpighian capillaries is associated with a scanty secretion of highly concentrated urine, which, too, is often copiously albuminous". In this he overlooks altogether the fact that the rate of flow through the renal vessels is much diminished in cardiac disease; while it is at least more than probable that the blood accumulates, not in the capillaries of the tufts, but in the venous plexuses on the farther side of them. It is not pretended that the blood-pressure in the renal glomeruli is the sole cause of the polyuria of the granular kidney; for while, on the one hand, it is impossible to believe that active secretion could be going on from a gland the secreting part of which was in a state of anæmia, the experiments of Heidenhain, Ustimowitsch, and Gritznér have proved the influence which urea, urates, etc., circulating in the blood, have upon the renal function, a fact which Dr. Johnson most properly regards as an important factor in the production of polyuria; but which the experiments of the last quoted observer prove to be totally opposed to Dr. Johnson's view, that the arterioles of the kidney are firmly contracted.\* Gritznér (Pflüger's *Archiv*, Band xi) found that, when he injected saltpetre into the blood, the renal nerves on one side only being divided, copious urinary secretion followed equally from both kidneys; but, when the general blood-pressure was raised by suspension of the respiration (with contraction of the arterioles, of course, throughout the body), the secretion of urine sank at once in the kidney the nerves of which were undivided; proving that the contraction of the renal arterioles, imagined by Dr. Johnson, is altogether inconsistent with the copious diuresis characteristic of this malady.

There is still one more anatomical point to which I must refer, and that is the increased permeability of the renal vessels which Thoma observed. This change was not susceptible of anatomical demonstration, but was very marked, even in parts of the organ apparently little affected by the degenerative process. The observations of Thoma and Ewald seem to weigh equally against the theories of Dr. Johnson and of Gull and Sutton; for their very careful measurements prove that the small vessels of the kidney have their lumina generally widened. If it could be proved, by careful injection, that there is anything approaching the nature of capillary atrophy present throughout the body, it would be a satisfactory solution of the problem; at present, I do not believe we have any precise knowledge of the nature of the general obstruction which leads to cardiac hypertrophy and increased

\* "There is evidence that the renal arterioles in these cases are more firmly contracted and more decidedly hypertrophied than those of any other organ or tissue." *Lumleian Lectures on the Muscular Arterioles*, p. 44.)

blood-pressure; but I think it is proved that, so far as the kidney is concerned, there is no shutting off of the blood from the glomeruli: and it is probable that, throughout the body, the obstruction is really in the capillary network, though whether that depends on structural alterations in the vessels or altered relations of osmosis between the intravascular and extravascular fluids, I will not attempt to decide, although the latter seems to me, in the absence of any anatomical facts, to offer a plausible explanation.

### SOME INDICATIONS FOR THE DIAGNOSIS AND TREATMENT OF AORTIC ANEURISM.\*

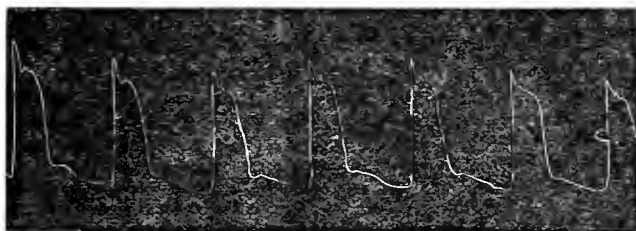

By F. A. MAHOMED, M.D.,

Medical Registrar to Guy's Hospital; Assistant-Physician to the London Fever Hospital; etc.

[Concluded from page 817 of last number.]

So far, two classes of cases have been considered: one in which both pulses were affected by the aneurism; the other in which the right was alone or chiefly concerned. A third class remains, that in which the right is unaffected while the left presents aneurismal characters; these cases are due to aneurism of the transverse arch or about the root or in the course of the left subclavian. Fig. x illustrates the

FIGURE X.—Aneurism of Transverse Aorta, slightly involving Orifice of Innominate (Mr. C. Heath).

1. Right. Pressure, 3 ounces. Indicates Hypertrophied Heart and very Degenerate Arteries.

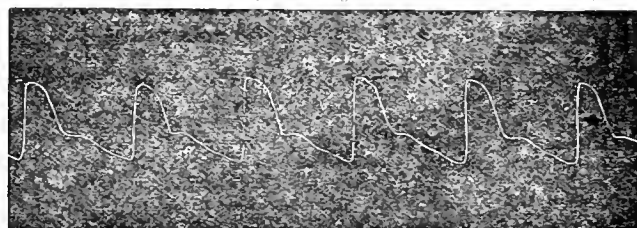

2. Left. Pressure, 1 ounce. Upstroke rather sloping. Percussion almost disappeared. Signs of Aneurism.

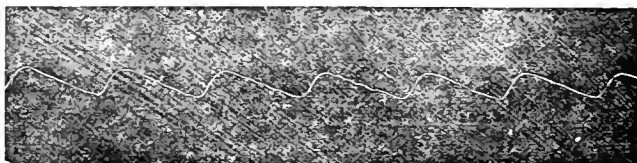

tracings obtained from a patient under the care of Mr. Heath with aneurism of the transverse part of the arch, which also slightly involved the orifice of the innominate. The chief disease, however, was situated in the transverse arch. The right radial tracing has no characters imparted to it by the aneurism, except a slight vibration or thrill imparted to it and visible on the summit of the tidal wave. The well-marked percussion, the height of the upstroke, the sustained and square-topped tidal wave, and the sudden collapse of this wave—all indicate an hypertrophied heart and a very degenerate and almost aneurismally dilated aorta, conditions which were found at the *post mortem* examination to have been present. The left pulse has many modifications produced in it by the aneurism; the upstroke is slightly sloping, percussion has disappeared, and all the waves are less distinct. The tracings would have indicated, had the question of distal ligation been raised, that the vessels on the left side of the arch should be tied if any operation were undertaken, which, however, the signs of general arterial disease exhibited by the right pulse rather contraindicated. In this case, the indication thus afforded, though correct, inasmuch as the chief sac of the aneurism was beyond the innominate and involved the transverse arch, still practically, as the innominate actually arose from immediately within the opening of the aneurismal sac, it would have been probably better to promote coagulation in this vessel, which might have extended into the sac, with which it was directly continuous.

A better illustration of the manner in which the left pulse may be

FIGURE XI.—Illustrates the Typical Effect of Aneurism on the Pulse. Aneurism of Left Subclavian Artery, involving Arch of Aorta (Dr. Broadbent).

1. Right. Pressure, 3 ounces. Indicates a somewhat Hypertrophied Heart and Degenerate Vessels.

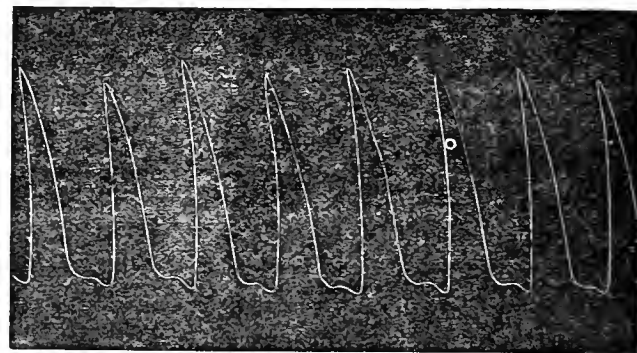

2. Left. Pressure, 2 ounces. Shows obliteration of all the Waves, sloping Upstroke, and uninterrupted Downstroke; the result of Aneurism directly in the course of the Vessel.

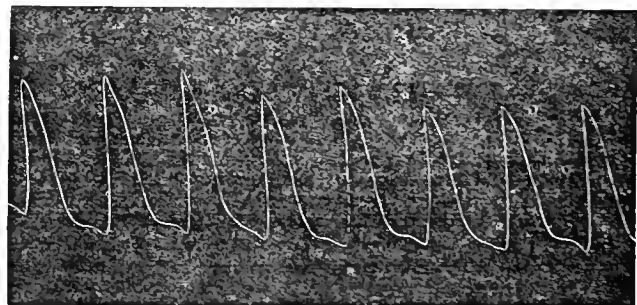

affected is seen in fig. XI, obtained from a patient under the care of Dr. Broadbent, but who subsequently died in St. George's Hospital. The physical signs in this case were those of an aneurism of the descending part of the arch, which, indeed, was the seat of the disease; but it extended as high as, and involved the origin of, the left subclavian; the only indication of this was afforded by the pulse, which is seen to be typically aneurismal on this side.

Occasionally, the mere proximity of an aneurism will affect the blood-stream, although it may not actually pass through the sac; so was it in a case, under the care of Dr. Broadbent, from whom the tracings in fig. XII were obtained. This was a case of aneurism

FIGURE XII.—Aneurism of Descending Arch of Aorta (Dr. Broadbent).†

2. Left. Pressure, 7 ounces. Shows a considerable diminution in size of Pulse and of all the Waves.

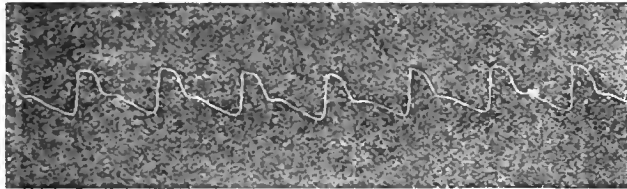

of the descending part of the arch, beyond the origin of the left subclavian. The left pulse is, however, distinctly affected by the aneurism, which appears to have partially diverted the stream from the left subclavian; the upstroke is shorter, the percussion-wave much diminished,

\* Read in the Section of Medicine at the Annual Meeting of the British Medical Association in Manchester, August 1877.

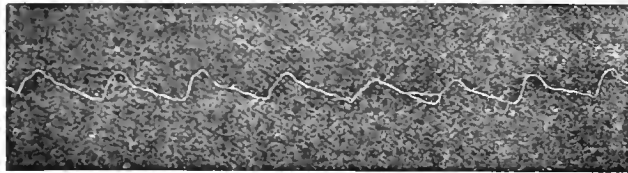

and the diastolic recoil less marked than in the right pulse, which is that of aortic regurgitation with hypertrophied heart. These tracings might have been most telling, as they would rather indicate an aneurism before the origin of the left subclavian, but the physical signs negatived this.

The tracings represented in fig. XIII were obtained from a very remarkable case lately in Guy's Hospital in the care of Dr. H. Bonfagge. In this patient, the only physical signs were those of pressure on the left bronchus, and it was impossible to say whether this was due to

FIGURE XIII.—Aneurism of Descending Arch, affecting Left Pulse.

1. Right. Pressure, 2 ounces.

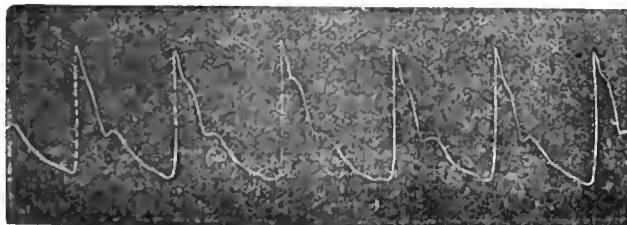

2. Left. Pressure, 3 ounces.

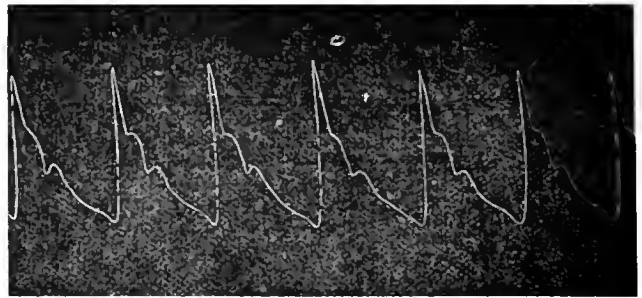

aneurism or to some other cause. Under these circumstances, the tracings of the pulse afforded actually the only guide on which to found a diagnosis; they were characteristic of aneurism. Neither pulsation, tumour, *bruit*, or area of dulness could be detected, and the general symptoms were only cough and pleurodynia. The sphygmographic diagnosis was confirmed three months afterwards by a *post mortem* examination in which an aneurism of the descending part of the arch was found projecting forwards and compressing the left bronchus. That an aneurism in this position should have so greatly interfered with the left pulse appears at first unlikely, but a careful search failed to detect any other cause for its diminution, and a consideration of the experimental results illustrated by fig. IV explains it; moreover, I have met with other similar cases.

In aneurism of the lower thoracic or abdominal aorta, the sphygmograph will not aid the diagnosis beyond affording a very valuable indication of the amount of general arterial disease and cardiac hypertrophy. In a recent discussion at the Clinical Society on the method of treating aneurism of the aorta by distal ligation of one or other of the large vessels taking origin from the arch, two points were especially commended to the attention of physicians: first, the importance of an accurate diagnosis of the exact position of the aneurism, and its relation to the great vessels; second, the necessity of ascertaining the extent to which general arterial disease exists. The preceding cases will, perhaps, permit a judgment to be formed as to how much the sphygmograph may assist in forming a conclusion on these points in any case. It is an assistance that we cannot afford to neglect. Physical signs are all alike liable to mislead in some cases; there is not one infallible; nor can the sphygmograph be considered so. In a few cases, it will give little or no help; in others, it will rather mislead; but in by far the larger proportion it proves itself of the greatest value. It may be well if a few instances of fallacy in a sphygmographic diagnosis be given.

FIGURE XIV.—Fallacy in Pulse-tracing. Deposit of Fibrin in Aneurism. Aneurism of Innominate Artery, nearly full of Clot, producing scarcely any diminution in Right Radial Pulse. (Mr. Cooper Forster).

1. Right. Pressure, 1 ounce. A very slight diminution of Percussion and Total Wave.

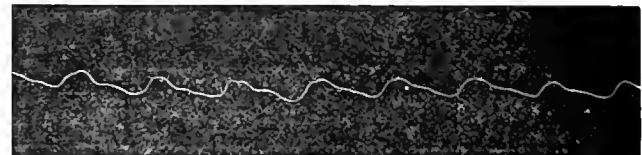

2. Left. Pressure, 1½ ounces. Indicates Hypertrophy of the Heart (which weighed 25 ounces).

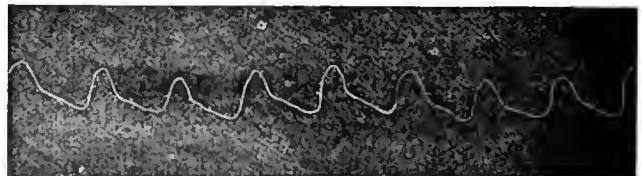

Fig. XIV illustrates one, which, however, under some circumstances may rather be taken as a most valuable indication. It proves that the presence of a large quantity of clot in an aneurismal sac may remove all indications of aneurism from the pulse. This is exactly what might be anticipated on theoretical grounds. The aneurismal pulse obtains its character from the presence of a more or less elastic sac, which diverts the blood-stream and absorbs the head-wave. Let this sac be filled up with firm clot, or its walls be even greatly thickened, and it must cease to produce the same effect on the stream. If, then, a pulse have been aneurismal, and gradually return to the normal, we are fairly entitled to assume that a deposit of fibrin is taking place in the sac. The tracings in fig. XIV were obtained from a patient under the care of Mr. Cooper Forster, who died shortly afterwards. A large aneurism of the innominate was found, having an opening into the aorta the size of a five-shilling piece. It involved half an inch of the carotid, but none of the subclavian. It was nearly full of old laminated clot, resembling soaked brown paper. The aorta was very bad, rough, and much calcified. There was great hypertrophy of the left ventricle, the heart weighing twenty-five ounces. In this case, the tracings from the two radials are almost exactly similar; that from the right being very slightly the smaller of the two, and having its percussion-wave a little diminished, but scarcely enough to found a diagnosis upon. Doubtless this pulse had presented much more marked aneurismal characters before the deposit of fibrin had taken place; but the patient was not then under observation.

Another fallacy occurs from the pressure of the aneurismal sac upon a vessel not itself affected. This is seen in the tracings in fig. XV,

FIGURE XV.—Fallacy in Diagnosis from Pressure of Tumour on Adjacent Vessel. Aneurism of Transverse Arch pressing upon Innominate, which was itself dilated (Mr. C. Heath).

1. Right. Pressure, 1 ounce. Highly Aneurismal, and smaller than left, suggesting Aneurism of Innominate as chief lesion.

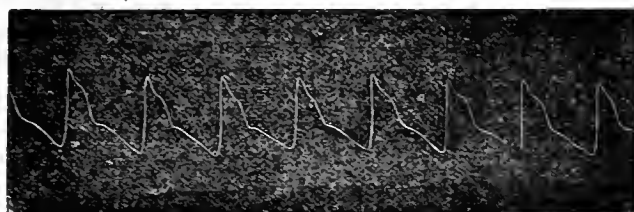

2. Left. Pressure, 1 ounce. Also highly Aneurismal from Aneurism of Transverse Arch.

obtained from a patient under the care of Mr. Heath. The tracings from both radials are highly aneurismal in their characters, that from the right being most so. A diagnosis was made of aneurism of the innominate involving the arch. At the *post mortem* examination, however, an aneurism of the transverse arch was discovered, compressing the innominate, which ran in its posterior wall, but was not itself aneurismal.

Again, the accidental plugging of a vessel beyond the aneurism may lead to error. The tracings exhibited in fig. XVI were obtained from a case in St. George's Hospital under the care of Mr. Rouse. The

FIGURE XVI.—Fallacy in Diagnosis from Accidental Plugging of a Vessel beyond the Aneurism (1). Case of Aneurism of Root of Right Common Carotid (Mr. Rouse).

1. Right. Pressure, 3 ounces.

2. Left. Pressure, 3 ounces. The Left Tracing is much the more Aneurismal; but this is probably due to plugging of the Left Subclavian Artery, as there is no pulsation in the Brachial.

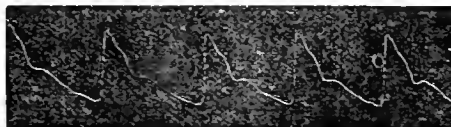

physical signs in this case—that of a young woman aged 18—indicated aneurism of the right common carotid. The tracings show a great diminution in, and aneurismal character of, the left radial pulse, which, if taken alone, would have led to a diagnosis of aneurism of the transverse arch, or about the origin of the left subclavian. No pulsation was discoverable, however, in the left brachial; and it is probable that this vessel had become plugged by an embolic clot. There does not appear any probability of an opportunity of examining the actual condition in this case; which, therefore, cannot be considered as altogether certain.

Diminution in calibre of a vessel, due either to endarteritic occlusion or to a tumour outside the vessel, may cause a diminution in the radial pulse resembling that produced by aneurism. Fig. XVII illustrates

FIGURE XVII.—Arteritis partially closing Subclavian Artery and simulating Aneurism. Left Subclavian Contracted to size of Radial (Dr. Moxon).

1. Right. Pressure, 3 ounces.

2. Left. Pressure, 3 ounces. Showing diminished Pulse-waves, especially percussion.

trates the radial pulses in a case of this description under the care of Dr. Moxon—one which I have already quoted in a former paper on this subject. The tracings, together with a *bruit* heard over the origin of the left subclavian, led to a suspicion of aneurism. Dr. Moxon nevertheless always regarded the case as one of angina pectoris, with aortitis: a diagnosis which proved to be correct, the difference in the radial pulses being well explained by endarteritic thickening found about the origin of the left subclavian, which reduced its lumen to that of the radial.

Other causes of fallacy might be enumerated. Among them are certain nervous conditions, affecting the vaso-motor nerves of one side and often accompanying hemiplegia. Anatomical abnormalities in the vessels of a limb are frequent causes for a diminution in the size of a radial pulse; but these can generally be detected by careful examination. By far the most abundant cause of error will be found, by the inexperienced, to be inaccuracy of observation from an imperfect application of the instrument. This practice alone can prevent; and that, combined with patience, will reduce it to an extremely rare mistake.

Time will permit but few remarks to be made on the indications for treatment afforded by the sphygmograph. If the relation of the condition of arterial tension to aneurism be considered, the value of the sphygmograph, which is undoubtedly the best and surest gauge we possess of this condition, cannot be overlooked. The amount of fullness or distension of the arterial system is necessarily of the first importance in the treatment of aneurism. Our aim should always be to reduce it as much as possible; in other words, to reduce the arterial tension. This is, in fact, the practical result of the admirable treatment laid down by Mr. Tuffnell. By tracings taken at intervals during the treatment of a case, it is possible to estimate the effect of our treatment in this direction with an exactness not often obtainable in medicine.

The methods which prove most efficacious in reducing tension under all conditions are as follows: a carefully regulated and but slightly nitrogenous diet; free purgation; free sweating by hot-air baths and other means; in some cases diuretics; and, under all circumstances, rest. Certain drugs, such as jaborandi, nitrite of amyl, and chloroform, have the property of reducing arterial tension. They do not, however, act in the same manner as the methods just mentioned, which actually reduce the volume and alter the character of the blood. These drugs act in a more or less temporary manner by relaxing the muscular coat of the arteries, and thus reduce their fullness by making more room for the blood they contain. Such remedies as these are especially indicated when temporary relief from an exacerbation of pain is required. Sudden reduction of tension is a certain method of relieving this, the most severe pain of aneurism, as surely as a sudden increase of tension, from exposure to cold or partaking of a heavy meal, will produce it. Other drugs are employed in the treatment of aneurism from their action on the circulatory system. Of these, aconite and veratrum may occasionally be employed with advantage to diminish the force of the cardiac pulsations. This is an effect which can be well demonstrated by the aid of the sphygmograph; but I have been unable to detect any effect on arterial tension produced by them. On the other hand, certain other drugs sometimes employed as vascular depressants are, I believe, fraught with the greatest danger, from the great increase of arterial tension produced by them; such especially are ergot and digitalis. Ergot, by contracting the muscular coat of the arteries, increases the tension as surely as others already mentioned decrease it; while digitalis not only increases the tension in a similar manner, but also so greatly increases the force of the cardiac contractions that an aneurism with thin walls might very readily be ruptured by its use. I have seen a pulse not only greatly increased in tension, but actually doubled in volume, by this drug. It is true that, when pressed rapidly to produce its extreme effect, the heart may be greatly slowed, and reduced pressure on the sac be possibly obtained; but I think the experiment too dangerous to be often justifiable. The drug which appears to produce beneficial effect in many cases of aneurism—I mean iodide of potassium—does not produce, as far as I have observed, any effect on the circulation appreciable by the sphygmograph; but there can be no doubt that it is most likely to act with advantage when the arterial tension has been reduced as low as possible. There appears to me, therefore, but little doubt that the most hopeful and rational treatment of aneurism is first to reduce arterial tension; to enforce absolute rest; and then to employ iodide of potassium with a view of causing contraction of, and therefore coagulation in, the sac. If these methods be not successful, appeal must then be made to the surgeon, and the questions of galvano-puncture and distal ligation be discussed.

Since this paper was written, I have employed another aid to the sphygmographic diagnosis of aneurism, which will, I think, prove of very great value. I have long desired a simple and effectual method of obtaining simultaneous tracings of the heart and pulse, by which it would be possible to measure "delay" in transmission of the pulse wave. Mr. Garrod, some years ago, made an ingenious modification of the sphygmograph, by which it was possible to obtain such tracings for physiological purposes; but, owing to the constrained position of the arm and for other reasons, his method was not well adapted for clinical observations. Dr. Burdon Sanderson has lately had constructed a miniature tambour, exactly similar to that which Marey employs for his polygraph; this can be attached to the frame of the sphygmograph, and made to record the movements of its lever on the slide immediately above those of the sphygmographic lever. The tambour is connected by a piece of India-rubber tubing with one of Dr. Sanderson's cardiographic air-pads, which is applied over the point of cardiac impulse and transmits the cardiac movements to the writing lever of the tambour. By this means, very excellent simultaneous tracings of the heart and pulse can be obtained.

Frequently, in cases of anæmism, the pulse is so slightly affected that it is impossible to state with any degree of certainty that its characters are due to the presence of an aneurismal sac, or that it has in any way been modified by it. If, however, we can demonstrate a greater delay occurring in the transmission of the pulse-wave on one side than on the other, it will go far towards establishing a diagnosis of anæmism.

There are several other interesting points in cardiac pathology upon which I have already obtained fresh light by this means; an account of these, however, I must reserve for a future occasion, that they may meanwhile be confirmed by further observations.

## CLINICAL MEMORANDA.

### MICROSCOPIC ORGANISMS IN MEASLES AND OTHER DISEASES.

IN reference to Dr. Braidwood's interesting paper on the microscopic characters found in tissues affected by measles, I wish to state that I observed bodies probably similar to those which he describes in the aqueous vapour of the breath of two cases of measles, and the same organism, which I called a "small-celled conferva", in the breath of a case of whooping-cough. A straight-celled confervous growth was also found in the breath of a case of diphtheria. These bodies were described in a paper "On the Organic Matter of Human Breath", read before the Literary and Physiological Society of Manchester in the year 1869, and published in their *Transactions* for that year. The paper was also published in the *Journal of Anatomy and Physiology* for May 1870. I did not venture to assert that there was anything specific in these organisms; but Dr. Braidwood's discovery of similar bodies in the lungs and liver would tend to prove that they have some important relation to the diseases in question.

ARTHUR RANSOME, M.D., Manchester.

### CHOLECYSTOTOMY.

IN the BRITISH MEDICAL JOURNAL of June 8th is the record of a remarkable case in which Dr. J. Marion Sims performed an operation for the relief of an obstructed gall-bladder. Dr. Marion Sims says, in his report of the case: "The question of surgical interference has more than once been raised, and recently Dr. Handfield Jones has revived the question in the *Medical Times and Gazette*, March 9th, 1878, page 247." It will interest Dr. Sims to know that "the advisability of an operation for the removal of gall-stones" was raised in the case of a lady seen by Mr. Maunder, in consultation with me, in October 1875, a full account of which will be found in the *Transactions of the Clinical Society of London*, vol. x, 1877, in a paper by me, which Mr. Maunder communicated on this very subject. Mr. Maunder had, previously to seeing the patient, practised the operation on the dead subject after the method which he had some time previously made known to the profession under the name of gastroenterotomy, or artificial anus in the small intestine. On the occasion upon which Mr. Maunder saw the patient with me, no tumour could be found in the region of the gall-bladder; and he, therefore, declined to operate at that time. I had frequently felt the gall-bladder in this case, containing some large hard substance—the stone found after death; but, on the day of Mr. Maunder's visit, it could not be felt. Others besides myself had felt it. To those interested in this subject, the whole history of my case, the *post-mortem* examination, the description of his proposed operation by Mr. Maunder, and the discussion upon it at the Clinical Society, will be found at length in the BRITISH MEDICAL JOURNAL of November 4th, 1876, page 604.

I think it is only fair to add that, from the above dates, the original idea of giving this operation a practical form is evidently due to Mr. Maunder.

FREDERICK H. DALY, M.D., Dalston.

## OBSTETRIC MEMORANDA.

### PREGNANCY WITH UNRUPTURED HYMEN.

I WAS summoned by a midwife the other night to see a case of protracted labour. She informed me that she could not feel the presentation, though she had been in attendance nearly twelve hours, and the pains were frequent and active. The patient was a strongly built, very stout woman, aged 29, in labour with her first child. I found the vulva unusually small, and the vagina was closed at a short distance by a dense concave membrane, with a central opening just large enough to

admit the point of the finger. By steady pressure, which caused considerable pain, I passed first one and then two fingers through the opening, and so reached the os uteri, which was high up and only slightly dilated, with the head presenting. It was some time before I realised the fact that this septum was the hymen, so firm and ligamentous was its texture, and its central perforation so small and rigid. I decided to wait and see how far the natural efforts would succeed in overcoming the unusual obstacle; and I had the satisfaction of learning that the labour terminated in eight hours after my visit, the septum having yielded rapidly before the advancing head.

HENRY TAYLOR, Guildford.

### NOTE ON PASSING THE UTERINE SOUND.

I HAVE seen certain cases in which it was remarked to me that "the uterine cavity was directed to the left side, and that the sound would not pass". In most instances, the difficulty has disappeared when I have turned the patient over upon her right side. Where the cavity is directed forwards, the woman is, of course, placed upon her back. This little manoeuvre has succeeded sometimes when I failed to restore the normal position by raising the fundus by my fingers in the vagina.

I think the practical bearings of this note, as regards both diagnosis and treatment, are obvious.

J. HICKINBOTHAM, M.D., M.R.C.P. Ed.,  
Physician to the Birmingham and Midland Hospital for Women.

### COMPLETE INVERSION OF THE UTERUS FOLLOWED BY PUERPERAL HYSTERITIS.

ON Tuesday, May 21st, I was called to Mrs. T., aged 23, multipara. She had been delivered on May 19th by a midwife of a living child. There was *post partum* hæmorrhage, which was controlled by the midwife. The patient complained of great pain until May 21st, up to which date the bowels had not acted, and the urine had only passed in small quantities. She said "something wanted to come away". On Thursday afternoon, whilst at stool, she felt something come down; the midwife, taking it for a dead child, tried to pull it away. Failing in this, she sent for me. I found the patient apparently moribund and quite blanched. On examination, I found the uterus inverted and extruded beyond the vulva. I attempted reduction, but failed. A few hours later, at a subsequent visit, after having got the vagina well on the stretch, I succeeded in effecting the reduction. I gave a grain of morphia hypodermically, and left. During the next four days, the temperature rose to 104 deg., there was great pain in the region of the bladder, and an extremely offensive discharge from the vagina. The patient is now doing well.

W. H. WRIGHT, L.K.Q.C.P.I.

## SURGICAL MEMORANDA.

### AURAL FURUNCULI.

THERE is a sign connected with boils in the meatus auditorius externus which, though very distinctive and highly important in a medico-legal point of view, has never, to my knowledge, been sufficiently dwelt upon by any writer upon ear-diseases, although every one conversant with these affections must have noticed it. I allude to the peculiar stain left upon the pillow-case by the thickened and comparatively scanty discharge that in some measure characterises a furunculus from an abscess. I have noticed it especially in children. The appearance presented by a pillow, the morning after a boil in the meatus has burst, is sufficiently characteristic to enable one to divine the nature of the affection from which the patient has suffered, for the pillow-case will be found studded over with stains so closely resembling linen-covered buttons, such as are worn on night-shirts, as to deceive, at a distance, the most clear-sighted. The thickened drop of discharge falls entire from the meatus upon the cover of the pillow, upon which the more liquid portion of the discharge spreads, leaving in the centre the more inspissated; this dries, and in drying gives, at a distance, an almost exact image of the shank of a button, the disposition of the surrounding stain rendering the appearance still more delusive. The subjects of the affection being rather restless in their sleep, roll their heads upon the pillow, so that by the morning it often happens that no two of the markings run together, but each one is separate, thereby rendering the resemblance to buttons additionally striking.

These umbilicated markings, especially if there be many of them, are a positive characteristic of the affection in question.

ROBERT T. COOPER, M.D. Dub.

## REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE  
HOSPITALS AND ASYLUMS OF GREAT  
BRITAIN AND IRELAND.

## GUY'S HOSPITAL.

## THREE CASES OF MALIGNANT PUSTULE OR CHARBON.

(Under the care of Mr. DAVIES-COLLEY.)

CASE I. (Reported by Mr. P. JACKSON.)—E. M., aged 43, a waterside labourer, was admitted into hospital on November 22nd, 1873, with the following history. He had never drank hard, and had been for two years a total abstainer. He had always enjoyed good health. For the last two or three months, he had lived badly. One week ago, he noticed a small pimple behind the left angle of the lower jaw. Four days ago, he began to feel ill. His appetite failed; he could not sleep; and his neck swelled rapidly. Two days ago, he began to suffer occasionally from difficulty of breathing.

On admission, the patient was anemic and weakly in appearance. One and a half inches behind the left angle of the lower jaw there was a slightly elevated patch of indurated tissue, and in the centre of this there was a thin dark scab, bordered by a purplish-red zone, around which the skin was of a pale yellowish tint. From ear to ear, beneath the chin, there was uniform swelling. The skin over it was somewhat reddened. There was no superficial oedema, and no separately enlarged glands could be felt. Oedema and a semi-fluctuating condition extended as low as the axillæ and nipples. The pulse was 110, very weak; the temperature 100.5 deg.; the tongue dry. A mixture containing iron and quinine was ordered him, with brandy and plenty of fluid nourishment.

November 23rd. He had had a very bad night, suffering constantly from vomiting. The swelling was extending to the face. Respiration was again troubled. The pulse was quick and hardly perceptible; the temperature 99.1 deg.; the extremities were cold.

November 24th. Respiration was very difficult. Tracheotomy was performed, which gave him for a time considerable relief. At 3 P.M., he died.

At the *post mortem* examination, which was made by Dr. Hilton Fagge, the starting-point of the disease was still marked as a purple patch, about the size of a penny, a little behind the left angle of the jaw. On cutting through this, the tissues beneath were found to be brawny and hard, and infiltrated with inflammatory products, but not in a greater degree than the rest of the neck and the upper part of the chest. Nowhere was there any tendency to suppuration. The muscles beneath were softer than normal. The facial and jugular veins were healthy and free from clot. The oedema extended probably along the planes of the cervical fascia, so as to reach the base of the tongue, the tonsillar and faucial regions, all of which were extremely oedematous. The entrance of the larynx was also very much swollen, and the tissues in the ventricles of the larynx were likewise oedematous, bulging above the vocal cords, which were free. The viscera were healthy, with the exception of the heart, in which there was some wasting of the musculi papillares.

CASE II. (Reported by Mr. ROWEOTHAM.)—J. F., aged 33, a worker in the tanyards amongst the hides, was admitted into hospital on December 20th, 1873. His health had always been good. For six years he had been an abstainer from alcoholic drinks. He had fed well, and worked until the day of admission among dry hides, which were often very offensive. Five days before admission, he felt an itching sensation on his chin. He scratched the place, and soon afterwards the swelling came, which gradually enlarged, without producing any constitutional disturbance.

On admission, he was well nourished, but somewhat anemic. In the middle of the tip of the chin there was a roundish black scab, and around this a crop of pearly vesicles. The adjacent skin was red and firm to about an inch from the edge of the central scab. The indurated tissue was somewhat elevated above the surrounding skin, but without any definite boundary. There was no evidence of suppuration or glandular infection. The temperature was 98.5 deg., and the general health good. Chloroform was administered, and nitric acid applied to the scab. As this produced little effect upon the indurated tissues, Mr. Davies Colley proceeded to excise the whole patch. No pus was found. The wound was then filled with chloride of zinc paste. No constitutional disturbance followed the operation. In a week, an eschar came

away; the wound granulated up rapidly, and, on January 8th, the patient went out well.

CASE III. (Reported by Mr. EWEN.)—G. J., aged 27, wharf-labourer, was admitted into hospital on April 7th, 1875. He had always enjoyed good health. On April 1st, he was landing some hides on a wharf, when he noticed a pimple upon his left cheek, which pained him. He scratched it, and the next day the pimple became larger. He went to a druggist, who gave him some ointment to rub into it. On the 4th, it became worse, and he again applied to the chemist, who strapped it up, and gave him some more ointment to rub in. On the 5th, when he awoke, the left side of his face was very much swollen. Fresh pimples had formed, and the glands under the jaw were painful and enlarged. He still went to work. The pimples turned black, and fresh ones appeared. The pain increased and extended to the back of his head.

On admission, his general health was good. There was a slightly elevated black scab on his left cheek, surrounded by small vesicles with red indurated bases. The skin around was red and infiltrated. There was no constitutional disturbance. Mr. Davies-Colley at once excised the whole of the indurated tissue, and filled up the wound with chloride of zinc paste. The patient would not have chloroform. Lint, soaked in carbolic oil, was then applied, and ten grains of quinine were ordered to be taken three times a day. On the 9th, the swelling of the glands had somewhat subsided. On the 13th, the slough separated, leaving a healthy granulating surface two inches in diameter. The swelling of the glands was diminished. He went out on the 30th, with a granulating wound of the size of a shilling; otherwise well. This patient stated that similar affections had occurred before among his fellow-workmen, and had been rapidly fatal.

Mr. Davies-Colley is indebted to his friend and colleague Mr. Jackson, who was at that time house-surgeon, for part of the reports of two of the cases.

REMARKS.—The disease, of which these three cases are examples, appears to be very rare in this country. Mr. Davies-Colley has, however, seen several other instances of it among the surgical out-patients at Guy's Hospital. This is probably due to the neighbourhood of the great leather-works in Bermondsey. In two of the cases described, there was a history of the patient having recently handled hides. The third was not improbably due to the same cause; but, unfortunately, the history only states that he had been working at one of the adjacent wharves. All the cases are very different from facial carbuncle, with which the disease has been often confounded. The absence of suppuration, and of the numerous openings characteristic of carbuncle, together with the presence of the black central scab, enable the surgeon to distinguish it readily from this affection. Occasionally, a primary syphilitic sore on the face may produce great swelling and induration, with a dark-coloured central scab. In such cases, also, there is very extensive enlargement of the submaxillary lymphatic glands. The rapidity, however, with which the charbon appears and grows, the history of infection with hides, and the great constitutional disturbance, prevent any confusion with syphilitic disease. In the first case, the swelling was too general and the patient too prostrate for any relief to be expected from excision of the focus of disease. The two other cases furnish examples of the efficacy of early removal, even when the oedema has begun to affect the surrounding healthy structures.

## CORK SOUTH INFIRMARY AND COUNTY HOSPITAL.

## CASES ILLUSTRATING ANTISEPTIC TREATMENT.

(Under the care of Mr. JAMES G. CURTIS.)

*Chronic Abscess of the Thigh.*—Mr. T. C., aged 79, of healthy appearance and no constitutional disturbance, was admitted into hospital on August 10th, 1877. He had noticed that, for about a year, a swelling had been coming on gradually in his thigh, reaching from the groin to the knee and encircling the limb for that distance; there was distinct fluctuation all over it. On the day after admission, Mr. Curtis aspirated the swelling and drew off seven pints of thin pus. He bandaged the limb gently. On the fourth day afterwards, in consequence of its filling again and that constitutional disturbance had set in, he made a free incision, about three inches, along the outer and depending portion of the thigh; evacuated all the pus, about four pints; and syringed well the entire cavity with carbolic lotion (1 in 40). This was all done under the carbolic spray. He put in two drainage-tubes, and dressed it antiseptically. This was continued daily for about six weeks, when the patient returned to his home cured.

*Compound Fracture of the Femur.*—E. M., female, aged 68, was admitted into hospital on November 12th, 1877. She fell from a cart the previous evening some distance in the country. On examination, Mr. Curtis

found the fibula broken about an inch and a half from its lower end, the internal malleolus protruding through the skin for about an inch and a quarter, the skin being drawn very tight around the bone. The foot was everted, and almost at right angles to the limb. Reduction had been tried before coming to hospital, without effect. Using the carbolic spray, he sawed off the protruding portion of the malleoli and replaced the bones easily. The wound was dressed antiseptically and put up in a McIntyre's splint. This treatment was continued for two months, when she left the hospital with an useful limb, partly ankylosed. The temperature during the entire treatment never exceeded 99 $\frac{1}{4}$  deg.

*Amputation of the Arm.*—J. M., aged 14, was admitted to hospital in October 1877. He had his right arm torn completely away, from about two inches above the elbow-joint, by a threshing-machine. Believing that, to have a case thoroughly antiseptic, the skin and tissues cut through in the operation must be healthy, Mr. Curtis operated, under the spray, about two inches above the wound, in healthy structures, and dressed it antiseptically. He again dressed it on the following day; and not again till the fourth day. On the fifth day after the operation, the little boy was up and out in the grounds. The wound required no dressing after the twelfth day, as it was perfectly cured. No pus whatever appeared during the treatment.

## REPORTS OF SOCIETIES.

### PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, MAY 21ST, 1878.

CHARLES MURCHISON, M.D., LL.D., F.R.S., President, in the Chair.

*French Millstone-Makers' or Builders' Phthisis.*—Dr. PEACOCK showed siliceous matter found in the lungs. The specimen was removed from the body of a man who died of this form of disease in the Victoria Park Hospital. The following are the particulars of the case. J. G., aged 29, was admitted into the Victoria Park Hospital under the care of Dr. Peacock on December 7th, 1877. He stated that he had been apprenticed to the trade of a French millstone-maker or builder at the age of 15, and had worked at it ever since. He had never had any serious illness before the commencement of the existing attack, nine months before his admission into the hospital. He said that he had always been a steady man, but subsequent information made the correctness of this report doubtful. He ascribed his illness to having taken cold from working in wet clothes. Five months before admission, he spat a single clot of blood; and four months before, he lost his voice, and had never recovered it. His appetite was defective, and he had sickness after food, and suffered from troublesome cough with much expectoration, and the face and extremities were livid. There was dullness on percussion at the upper parts of the chest, with bronchial or cavernous respiration, and rhonchus in all parts. There was also dullness and bronchial respiration in the right dorsal region. On the 17th, without any obvious cause, he had a severe attack of dyspnoea, during which he was very livid, and he became much exhausted after it, and died on the 20th. On *post mortem* examination, there were firm adhesions between the lungs and the parietes at the upper parts of the chest on both sides; and there were numerous cavities in the lungs, and especially a large one at the right apex. The lower part of the middle lobe of the right lung was in the state of grey consolidation, and was so firm as to be with difficulty broken down. The bronchial mucous membrane was reddened and villous. Some of the bronchial glands were much enlarged and very hard. The right vocal cord was entirely destroyed. The heart was large, weighing twelve ounces and a half; there was no valvular disease, but its cavities were dilated. The kidneys were healthy; the liver somewhat small. Portions of the indurated lung-tissue were examined by Dr. Bernays in the Chemical Laboratory at St. Thomas's Hospital. The ash was found to contain 0.400 per cent. of silica. Dr. Sharkey also examined portions under the microscope, and found it to have extensively undergone the fibroid change. Attention was first attracted to the frequency of pulmonary disease in the men engaged in millstone-making or building by Dr. Peacock in a paper in the *British and Foreign Medico-Chirurgical Review* in 1860; and the cases which he then reported are very similar to the present one and others since placed on record. The men employed in the trade state that, if they begin the work in early life, they seldom live for more than a few years; and, if they take to it later in life, they rarely survive beyond forty years of age; and this is confirmed by Dr. Peacock's observations. The ages of the two patients whose cases are related in his first paper were twenty-three and thirty-seven. The subject of the present case was twenty-nine; and, of twenty-eight

men whom he then found at work in different yards who had been apprenticed to the trade, the oldest was only thirty-eight years of age. A patient, whose case was related in a former volume of the *Pathological Transactions*, was forty-eight; and one who died some little time ago in the Victoria Park Hospital under Dr. Andrew, and whose case is referred to by Dr. A. Shepherd in his Goulstonian Lectures, was forty-five; but in some instances, when the men find their health beginning to fail, they leave the trade and work as engineers in corn-mills, where they are only occasionally employed in dressing the stones, and so their lives are prolonged. The appearance of the lung to the naked eye is well shown in the eleventh plate of Dr. Shepherd's lectures, and the microscopical appearances in the twelfth plate. The drawing taken from the case which occurred at the Victoria Park Hospital under Dr. Andrew.—Dr. DOUGLAS POWELL asked if this form of phthisis gave any hereditary taint. In dust-phthisical patients, the parents often entered the trade late in life; while their children, being put to the trade early, die young.—Dr. PEACOCK replied that he could not say exactly; and, in answer to a question put by Dr. C. T. Williams as to the morbid appearances, said that there were no cavities in the lungs, but hard masses. It was really fibroid phthisis, and was not rapidly fatal.—Dr. LEARED said he had seen a case with a sac in the lung.

*Carcinoma (Forty-four Years after Removal) of Orbit.*—Mr. NETTLESHIP related the particulars of a case where an encephaloid cancer of the orbit had been removed by Mr. Lawrence fourteen years ago, and where the patient had recently come under his care. She was free from symptoms for four years, and then a small encapsulated tumour of the skin formed, which was removed. A growth recently showed itself at the seat of the original tumour, which was removed in consequence of the pain it caused. It was adherent to the orbit, and displaced the eyeball. There was a little tumour near it. The contents of the orbit were removed, and chloride of zinc paste applied. The case did well. Carcinoma of the orbit was rare; and in this case the interval was very long. The two masses were adherent to the bone. It was a carcinoma, like scirrhus of the breast, and the cells were larger than those of a healthy lacrymal gland.

*Tumour of the Sclerotic.*—Mr. NETTLESHIP said that some time ago he removed a tumour of the sclerotic. Afterwards, the thyroid gland enlarged, and tumours grew elsewhere, and the patient died.

*Cerebral Embolism.*—Dr. CAYLEY described a case in a woman aged 52, who had chronic bronchitis, and became unconscious suddenly. She was not paralysed, but had difficulty in speaking afterwards. There was no facial paralysis. The right foot twitched outwards, the great toe being most affected. The heart was enlarged, and its action irregular; while its sounds were rough. The twitching of the right foot grew less. Then there was great pain in the legs, which became gangrenous. Then, erysipelas set in, and the patient sank. There was found at the necropsy an old thrombus in the left auricle. Both femoral arteries were blocked by clot; and there was a patch of red softening in the inferior left parietal convolution. There was mitral stenosis.—Dr. DOUGLAS POWELL said that mitral stenosis often ended in embolism.

*Anatomy of Dysidrosis.*—Dr. TILBURY FOX exhibited some sections from a case of dysidrosis in its initial stages. He said there was no eczematous inflammation. It was an affection of the sweat-apparatus. There was tumefaction of the skin; and the mouths of the sweat-glands were open. The sweat-ducts were large; the "sago-grains" were in the line of the sweat-ducts, and were globular dilatations. As to the deeper changes, the glands were thickened and stuffed with epithelial cells.—Dr. F. TAYLOR asked if there were inflammation or obstruction of the sweat-ducts. The fluid being alkaline and albuminous, pointed to inflammation.—Dr. FOX said it had been described as an inflammation.

*Elongated Cavity in Spinal Cord.*—Dr. F. TAYLOR exhibited a spinal cord from a child which suffered from chronic hydrocephalus, where there was a cavity which was not a dilatation of the central canal. It occurred in the dorsal region. It was two inches and a half long, irregular in shape, and in the posterior portion of the cord. It was independent of the central canal in places. It only had epithelium lining in patches. The tissues of the cord around were fibrillated. There was another small cavity near. The origin of these cavities was doubtful. They were not due to inflammation, and there was no tumour. They seemed rather due to some degenerative changes.

*Ovarian Cysts from Bodies of Twin Infants.*—Dr. LEARED gave an account of ovarian cysts in twins, the offspring of a healthy mother. They did not thrive, though healthy-looking when born. One had cough, and was jaundiced from birth. It had white stools. It was found that the gall-bladder did not open into the bowel. In one ovary was a cyst of the size of a filbert; in the other ovary was a lesser cyst.

The other child died of pneumonia. A cyst of the size of a pea was found in each of its ovaries. These cysts were congenital.—Dr. S. WEST had also seen a case where there were cysts in both ovaries.—The PRESIDENT inquired if there was any history of syphilis.—A negative answer was returned.

*Spontaneous Rupture of Oesophagus.*—Mr. W. ADAMS (of Harrington Square) exhibited an oesophagus from a gouty gentleman aged 53, who was subject to dyspepsia and vomiting. He was well on the day of his death, and ate a hearty lunch of beef-steak. After awhile, he was faint, and retched, then shrieked, turned pale, and complained of acute pain in the left side. He became collapsed, and his breathing was hurried. He died in seven hours. At the *post mortem* examination, a rupture of the oesophagus above the diaphragm was discovered, and the contents of the stomach were found in the left pleural cavity before the abdomen was opened. Amidst the contents of the stomach, was a large piece of gristle, which probably was the cause of the rupture. The pyloric end of the stomach was thickened.—In answer to questions, Mr. ADAMS said there was no disease of the stomach, no *post mortem* digestion, and no hæmorrhage.—The PRESIDENT said it would be well to submit the oesophagus to a Committee to investigate the condition of its tissues.—This was done.

*Aneurism of Pulmonary Artery.*—Dr. S. WEST exhibited a specimen. It came from a woman aged 46, who was found dead in a pool of blood. She had previously had slight hæmoptysis. On *post mortem* examination, the left lung was found normal, except some pleuritic adhesions. The right lung had merely two patches of induration in it; one at the apex, the other at the base, the latter being of the size of an orange. They consisted of connective tissue. Each contained cavities, those of the basal mass being largest. In one of these, the size of a walnut, was found blood and an aneurismal sac connected with a large artery.—In answer to Dr. H. GREEN, Dr. WEST said such a condition was rare; and, to a remark by Dr. POWELL, that the cavity was larger than the aneurism.—Drs. CROCKER and C. T. WILLIAMS spoke of the occurrence of aneurisms in lung-cavities; several such aneurisms being at times found in the same subject.

*Filarious Disease.*—The PRESIDENT laid before the Society, for Dr. BANCROFT, the discoverer of the *filaria sanguinis*, a pamphlet giving an account of thirty-one cases of disease caused by these filaria. There were cases of chyluria, hæmaturia, inflammation of the lymphatics, elastic tumour, and other diseases in the list.

*Elephantiasis of Clitoris.*—The PRESIDENT exhibited, for Dr. LONDON of Carlsbad, an enlarged clitoris, weighing two pounds, which had been successfully removed.

*Polypus from Nose, Antrum, and Orbit.*—Dr. POWELL, for Mr. SPENCER WATSON, described a round-celled sarcoma from a man aged 59. The left nostril was obstructed, and the left eyeball displaced. It had grown in six months. Previously to this, the patient had excellent health. There was no history of injury. It was partially removed; but the patient died.

*Colloid Cancer of the Breast.*—Dr. POWELL, for Mr. WATSON, described a tumour which had existed for fourteen years in the breast of a woman of florid complexion. It remained long and quiescent, and then grew and became painful. In January 1877, it was of the size of a hen's egg. It was removed, and there was no return of it so far. Colloid cancer of the breast was rare.

The meeting then adjourned till the next session.

The PRESIDENT said he hoped those members who had not sent in their papers to the Secretaries would do so without delay, in order that the *Transactions* might be proceeded with.

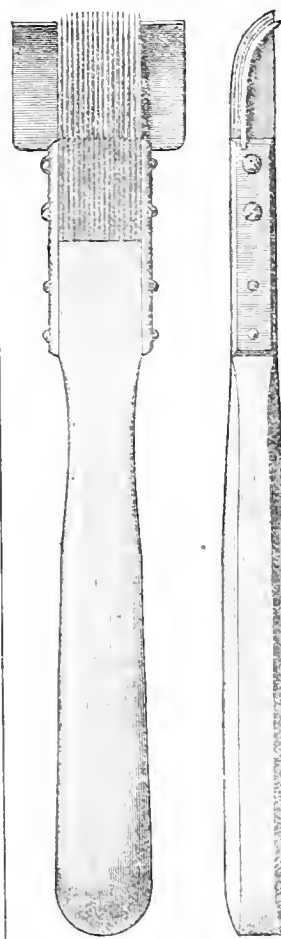

## MEDICAL SOCIETY OF LONDON.

MONDAY, MARCH 18TH, 1878.

ERASMUS WILSON, F.R.S., President, in the Chair.

*Two Cases of Port-wine Mark Treated with a View to Obliterating the Mark without Scar.*—Mr. BALMANNO SQUIRE reported these cases. One case was that of a man aged 30; the other that of a woman aged 55. In the last case, the port-wine mark was confined to its usual situation, namely, the right half of the face, the greater part of the front of which it occupied. In neither case did the patient continue under treatment sufficiently long to allow the obliteration of the whole of the port-wine mark; but in each a considerable portion of the mark was eventually completely obliterated without the production of any scar. The means adopted was the scarification of the flat nævus by means of parallel incisions effected with a frozen scalpel, the skin also being frozen by means of the ether-spray. The parallel incisions carried as deep as the entire thickness of the skin proper were spaced as close together as the sixteenth of an inch. As soon as these had

(within three or four days) completely healed, a second set of parallel incisions was made, the direction of the second set of incisions being made obliquely to the direction of the first set; and so on with a series of operations. In this manner, after about ten sets had been made, the port-wine mark had become permanently and considerably fainter, and yet without any trace remaining of the numerous incisions that had been made. The portions of the mark operated on were eventually completely obliterated without scar. Mr. Squire exhibited water-colour

drawings of the two cases thus operated on, and also pen and ink sketches of an instrument he had devised (made for him by Messrs. Weiss) for executing a series of incisions at one stroke. This instrument was like an ordinary scalpel, only that it had sixteen parallel blades instead of one. These blades were so thin, and placed together so closely that eighteen of them measured only half-an-inch across. Mr. Squire also described an apparatus consisting of a number of parallel needles fixed in a plaster-of-Paris handle, so that the handle contained thirty-six needle-points in the half-inch square. If these were heated red-hot and thrust into the skin, they produced complete sloughing of the entire area operated on. But, if they were heated to only black heat and their introduction into the skin was effected only momentarily, they produced only a stippling of minute punctiform scars. His experience was, on the whole, in favour of the multiple parallel linear scarifications made with chilled steel, as first described, rather than of the multiple punctiform operation with black-hot steel.—The PRESIDENT said that the operation was obviously as yet only in its infancy, but that the process of linear scarification as proposed by Mr. Squire appeared to promise good results. Certainly no other satisfactory mode of dealing with port-wine mark had as yet been proposed.—Dr. MORRIS had attempted an operation on a port-wine mark with the single scalpel as at first advocated by Mr. Squire, but had found difficulty in executing the incisions with the requisite nicety. He had accordingly devised a multiple scarifier, which he exhibited (made for him by Mr. Hawksley). He had tried this instrument also on lupus erythematosus, and also on cases of acne rosacea. His experi-

ence, so far as it had gone, confirmed the researches of Mr. Squire.—Mr. WORDSWORTH agreed with Mr. Squire in preferring a black heat to a red heat in operating by the needle process. He had long employed in cases of port-wine mark a solitary needle bearing a ball of steel around the needle placed at about three-sixteenths of an inch from the point, so as to retain heat; this ball enabled a rapid series of punctures to be effected with the needle without loss of its heat.—Mr. DAVY had treated a case of port-wine mark with some success on Mr. Wordsworth's plan.—Mr. B. SQUIRE replied that, in order to succeed in effecting neatly close parallel incisions, some practice in pencil or in pen-and-ink drawing was a considerable advantage, and that those practitioners who happened to have this kind of training would find but little difficulty in the matter. However, the multiple scarifier he had devised would dispense with the necessity of that kind of accomplishment. He had tried multiple linear scarification in lupus erythematosus, but preferred the results he had obtained in that disease by erosion with a minute sharp steel spoon. The spoon in such cases had also been tried with good results by Dr. Auspitz and by Dr. Hebra junior. In the "teleangiectasis" which often accompanies acne rosacea, he had often employed linear scarification as proposed by himself with better results than the multiple punctiform scarification recommended in such cases by Hebra senior. Professor Vidal of Paris had recently adopted Mr. Squire's method of linear scarification in cases of lupus vulgaris with apparently excellent results. Dr. Dubini (of Italy), and after him Dr. Volkmann (of Halle) had proposed multiple punctiform

scarification in cases of lupus vulgaris; but no one, so far as could be ascertained, had proposed the bolder method of linear scarification in lesions of the skin, and this was more uniform and more thorough in its effect. Moreover, scarification of any kind, as applied to port-wine mark, was, he believed, as yet untrodden ground.

### BRITISH MEDICAL ASSOCIATION.

#### ABERDEEN, BANFF, AND KINCARDINE BRANCH.

WEDNESDAY, APRIL 3RD, 1878.

FRANCIS OGSTON, M.D., President, in the Chair.

*Calculi.*—Dr. HIRSCHFELD (Banff) showed several specimens of urinary calculi which he had removed. In one case, the patient, a man aged 73, suffered from intense itching. As soon as he recovered from the chloroform after operation, the itching was found to be entirely gone, and did not return. He made a good recovery. He had never taken morphia.

*Gangrene.*—Dr. HIRSCHFELD showed part of the foot of a man aged 37, which he had amputated for gangrene.

*Fibroid Polypus of Uterus.*—Dr. HIRSCHFELD showed a specimen of fibroid polypus from the uterus of a woman whose chief symptom was profuse hæmorrhage, which was completely relieved by the removal of the polypus.

*Tumour of the Head.*—Dr. HIRSCHFELD showed a tumour which he had removed from the head of a lad aged 19. The tumour, which covered the head like a Scotch bonnet, was congenital, but had increased very much lately. It was supposed to be fatty, but was really hypertrophied tissue. A large elliptical portion was cut out, leaving sufficient skin to cover the scalp. An opening in the skull existed posteriorly, through which pulsation was seen and felt. The case was doing well.

*Chrysophanic Acid in Psoriasis.*—Dr. OGILVIE WILL read a paper on the use of chrysophanic acid in psoriasis, with notes of six cases in which it had been employed by him. Five of the cases had been treated in the Royal Infirmary, and one was a private patient.—Case I. was that of a boy aged 14, who had different forms of psoriasis over the greater part of his body, including his scalp. He was ordered the chrysophanic acid ointment (fifteen grains to an ounce of hot lard) night and morning; and in about ten or twelve days a cure was effected. As during his residence in hospital the back on one occasion looked suspicious, one application was made after this, but no further eruption took place. He was kept under observation six weeks, and was directed to take Fowler's solution for some weeks after leaving hospital.—Case II. A lad aged 17 was seen after the psoriasis had existed eighteen months over the greater part of the body. The corium in this case was not so much thickened as usual. On the sixth day after the application of the acid, most of the scales were gone; and on the eighth all had disappeared; and, after less than three weeks, all trace of disease was lost. He had a warm bath after the first eight days.—Case III. A girl aged 17 had psoriasis of six months' standing, and specially affecting the limbs, where there was excessive thickening of the corium. After four days of the acid, the scales began to fall off; and in about a fortnight the infiltration had greatly lessened, even in the larger patches; and in about a month there was none of the eruption to be seen. After the first fortnight, this patient had a warm bath, and the strength of the ointment was increased to twenty grains to the ounce.—Case IV. A female aged 12 was treated by the acid for psoriasis on the legs, knees, and arms, the duration of which was unknown. After ten days' treatment, the disease completely disappeared.—Case V. A girl aged 13 was admitted with well marked psoriasis of six weeks' standing. The eruption affected, to a considerable extent, the whole body, but was chiefly conspicuous on the knees and elbows, where infiltration was considerable. At the end of a week, all the scales had gone; and at the end of three weeks she was dismissed perfectly cured.—Case VI. A young man aged 22 had had psoriasis of many years' standing, affecting particularly the front of legs, chest, and forearms, with much thickening and but little redness. The ointment (twenty grains to the ounce) was used; but, after application for ten days, heat and tingling set in in various parts, particularly in the axillæ. A warm bath, and avoiding the irritated parts till the inflammation subsided, with a more limited use of the ointment in other parts, caused the irritation to subside in a few days, and the epidermis of the inflamed parts to peel off; and at the end of three weeks nearly every part was sound. When last seen, he was well, except over the scalp, where, owing to his leaving for a voyage and not being able to shave the head, the ointment had not been applied. He was ordered Fowler's solution at his last visit. The author concluded by calling attention to the

rapidity and satisfactory nature of the cure in the cases. He directed attention to the strength of the ointment used as being important, not only for economy, but on account of the irritating character of the strong ointments. As to the permanence of the cure, he was rather doubtful if any remedy could be relied on as producing permanent results in the disease. He was with this remedy able to promise at least temporary relief in a very short time; and he thought the disease might be kept from returning by small doses of arsenic. The objections to the mode of treatment, he stated, were: 1. The irritation caused; 2. The staining of the skin; 3. The staining of the clothing and bedclothes. In respect to the first, enough had been already said to show how that disadvantage could be overcome; the second was only a matter of time, as, after the shedding of the epidermis (not a long process), the skin was purer than before treatment; and, as to the third, bleaching powder carefully used removed all stains from clothing or bedclothes without injuring them.—Dr. A. OGSTON did not think the return of the disease any real objection, for under every remedy the disease returned. He had tried the remedy, and had been struck with its effects. He had not given any internal medicine when using the acid, but had used it alone. He had failed with it in a case of chronic eczema of the head, but considered that this was owing to not having continued the remedy sufficiently long. He had tried a much stronger ointment than fifteen grains to the ounce in a case of pityriasis versicolor; and, although the irritation produced was excessive, there was a complete cure after warm baths had been employed. His ointment in this case had contained two drachms to the ounce.—Dr. URQUIHART corroborated the author's statements as to the success of the remedy, so far as he had seen it tried.—Dr. STEPHENSON asked if the skin where the patches had been was always white, or became purple from the use of the remedy.—Dr. WILL, in reply, said he had found salicylic acid to cure eczema capitis very quickly; and that oleate of mercury was in his hands very successful in cases of pityriasis versicolor. Replying to Dr. Stephenson, he stated that the patches of skin under where the psoriasis spots had been were not stained but were white; it was the surrounding skin which was stained. He mentioned that benzole on blotting paper appeared to remove chrysophanic acid stains from the fingers. He had cured tinea tonsurans in a fortnight with chrysophanic acid.

### BRITISH MEDICAL ASSOCIATION.

#### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

FRIDAY, MAY 24TH, 1878.

N. P. BLAKER, Esq., in the Chair.

*Orbital Tumour.*—Mr. PENFOLD of Brighton showed a photograph of a tumour in the left orbit occurring in a married woman, and related its history and treatment. It commenced to grow six or more years ago, and caused but little failure of sight, health, local pain, or inflammation until very recently, when vision became slightly dim, and she suffered at times from considerable frontal pain. In June 1877, when he first saw her, the growth was increasing in size and pushing the eye outwards. A grooved needle introduced deeply into the substance of the former proved it to be solid. The tumour, together with the eyeball, was subsequently removed, and the former was found to spring by a broad base from the periosteum at the bottom of the orbital cavity. The muscles were involved in the growth, and the latter could not have been removed without sacrificing the eye. The woman soon recovered from the immediate effects of the operation; and when he saw her in April last, eleven months ago, he observed no outward or visible sign of any return of the disease. Portions of the removed morbid growth being afterwards carefully examined, showed that it had a delicate investing capsule, and that its structure was fibroid.

*Hemiplegia and Apoplexy from Embolism.*—Dr. WITHERS MOORE related a case of hemiplegia and subsequent apoplexy from embolism, which occurred in his practice at the Sussex County Hospital. The patient, a married woman aged 35, had always enjoyed good health—save being subject at times to rheumatism—until about two months before the present illness, when she began to fail, complaining of giddiness and inability to sit up to do anything for any length of time. Six days before admission, she for some hours wandered in her ideas; but there were no paralytic symptoms. Two days later, she felt better and more cheerful; but in the evening, whilst walking across the road, she fell down, but did not lose consciousness; picking herself up immediately, she walked home to bed, and very soon afterwards told her husband that she had had a fit. The left extremities were powerless and stiff; the mouth was drawn to the right side, and speech was less plain than usual; the tongue also had been bitten during the fit. On admission, it was ascertained that she had always been a steady woman.

She was fairly intelligent, though memory was slightly defective. There was loss of motion and rigidity in the left arm and leg; sensation also was impaired. The left side of the face was paralysed, and the tongue protruded towards the left side. Deglutition was difficult. Temperature 99 deg. The heart-sounds were normal. Pulse 90, regular. The catamenia were present. Micturition was involuntary; the urine was of specific gravity 1026, acid, with no albumen. She continued in much the same state, taking food fairly, until the twelfth day of her residence in the hospital. The limbs were then as powerless as before, but less rigid, and she complained of pain when she was moved. The left arm was very sensitive. She was very complaining, obstinate, and manifestly weak in intellect. She slept better with the chloral draught. Pulse 92. The appetite was good; the bodily functions regular; but she passed her urine involuntarily. On the evening of the same day, whilst the nurse was turning her over for the night, she resisted as usual, and suddenly became unconscious, breathing stertorously. There were no convulsions. When seen by the house-surgeon, Mr. H. Smith, the eyes and face were turned to the left side; the pupils were rather dilated, but equal and active; the face and neck were rather flushed. She could feel when pinched on the right side, moving the limbs slightly; but the right arm was now rigid and flexed across the chest like the left, and was almost powerless. There were occasional twitchings of the muscles of the face. On the morrow, all these symptoms were intensified, the pulse going up to 154, and the temperature to 101.4 deg. Next day, the pulse was 182, and almost imperceptible. The face was livid; the pupils were fixed; the respiration gasping; the limbs were relaxed. The temperature in the axilla was 108.2 deg., going up in an hour to 108.9 deg., when death ensued. A *post mortem* examination was made twenty-four hours after death. The pia mater was slightly injected, with here and there some small patches of capillary congestion. The basilar artery contained a little hard white fibrinous clot; the right carotid at the base of the brain contained a similar but more elongated clot. The left carotid, middle cerebral, and posterior communicating arteries contained several firm decolorised fibrinous coagula. In several parts, the coats of these arteries were thickened. The surface of the brain was soft; the deeper part of the grey matter of some convolutions of the right anterior lobe had a decidedly yellow tint. The right centrum ovale minus appeared of a purple or pinkish colour from congestion of puncta vasculosa; and at one spot of the middle lobe close to the longitudinal fissure was a patch of capillary ecchymoses. The consistence of the cerebral substance, except at the surface, was normal. On the under surface of the cerebellum, close to the fourth ventricle, were two small granular masses. There was nothing calling for remark in the other organs, save that there was slight thickening and opacity of the anterior flap of the mitral valve, and the endocardium was puckered and stained from decomposition. In this case, the left side of the face and tongue being affected, as well as the corresponding side of the body, indicated that the seat of disease was above the pons Varolii. The age of the patient and the fact of the first attack occurring without loss of consciousness, merely confusion being present, pointed to embolism rather than to hæmorrhage. The slight pyrexia and contraction of the affected side implied that an attempt was being made to establish the collateral circulation, congestion resulting. The most notable points in the second attack, two days before death, were: the conjugate deviation of eyes and turning of the head towards the paralysed side; the activity of the pupils; and the disproportionate rapidity of the pulse—this last pointing to some paralytic lesion near the origin of the vagus. The rigidity at the time of attack was important, as confirming the present view of its being a sign only of some extensive injury to the brain, and not necessarily of hæmorrhage into the ventricles. The great rise of temperature in the last hours of life was remarkable, and must be attributed to increased nutritive changes due to vaso-motor paralysis allowing active dilatation of the arterioles, and not, as some would say, to paralysis of the hypothetical thermal centre. The accord of the symptoms during life with the *post mortem* appearances was duly noticed, as also the powerlessness of any treatment save a supporting one in such cases.

#### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, MARCH 6TH, 1878.

SAMUEL GORDON, M.D., President, in the Chair.

*On the Distribution of Cholera in Dublin in 1866, and its Relation to the Geological Formation of the Dublin District.*—Dr. GRIMSHAW read a paper on this subject. In May 1875, when reading Dr. Himes's translation of Professor Pettenkofer's observations on cholera, it occurred to him that a careful investigation of the relations between the

distribution of cholera in Dublin and the geological structure of the site upon which Dublin stands might tend to throw some light on the promoting causes of cholera, and serve also as a test of the truth of some of the views put forward by Dr. Pettenkofer. Munich, where Pettenkofer's views were tested, is situated on a porous gravel-bed permeated by air and water. The spaces between the gravel in such a bed afford opportunities for the accumulation of foul air and foul water derived from excrementitious or decomposing matters cast upon the surface. Comparing Dublin with Munich, it is found that in Dublin these conditions are fulfilled, although in a somewhat different manner. Some short time ago, it was considered that the whole of the Dublin district—namely, the city and its immediate suburbs—consisted of boulder-clay resting on limestone. Hence, when Dr. Grimshaw first investigated the question, it appeared to him that, as this boulder-clay is an impervious stratum, the experience of Dublin was at direct variance with that of Munich. On further inquiry, however, by the kindness of Mr. Hull and Mr. Cruise of the Geological Survey of Ireland, he found that recent observations had shown that this is not true, but that a considerable portion of the district is situated on gravel which is superimposed on the stratum of clay previously mentioned. This gravel-bed was once the bottom of the sea, and consists of a raised sea-beach which extends along a considerable portion of the east coast of Ireland. The parts of Dublin and of its vicinity which rest on this "littoral" gravel-bed having been described, Dr. Grimshaw proceeded to analyse—1. The number of deaths, and the rate of mortality per 10,000 living, from cholera; 2. The proportion of the inhabited area situated on gravel; and 3. The estimated population of each of the registration districts in the city of Dublin and its suburbs in 1866, the year of the last epidemic of cholera. It appeared from this analysis that the greatest number of cholera deaths occurred either on pervious strata (the gravel-bed), or close to the old river-courses. In his paper, the author held that cholera is a contagious disease, and that it will spread if suitable conditions—of traffic, place, time (season), and individual, as laid down by Pettenkofer—are provided. In conclusion, Dr. Grimshaw considered that the result of his inquiry confirmed, to a great extent, the observations of Pettenkofer, and pointed to the dangerous ground upon which a large portion of the city of Dublin and its suburbs stands. This dangerous ground is steadily becoming more dangerous as the saturation of the gravel with sewage increases. It is, therefore, essential to the health of the people of Dublin that sewage should be kept out of the gravel-bed, and further that all communication between the poisonous atmosphere contained in the interstices of the gravel and that of the houses built thereon should be cut off. It was not the author's duty to point out the remedies, but he ventured to remark that any system of main-drainage for Dublin which does not effectually prevent the admission of sewage to the gravel-bed, will fail materially to improve the health of the inhabitants of the Dublin district.—Dr. LALOR thought that the paper omitted a most important factor in the spread of cholera—namely, contagion. As to cholera taking the course of old river-beds, he objected to any general conclusion on that point drawn from the experience of the outbreak of 1866; he also objected to any conclusion being founded on a vague use of the term "gravel", and, above all, to any conclusion as to the propagation of cholera by water-courses without account being taken as to whether the water-course was a real river or a sewer, like the Liffey or the Dodder.—Dr. H. KENNEDY would be slow to accept the contagion theory with respect to cholera; and would refer to the frequent simultaneous existence of epizootics and of epidemics.—Dr. DARRY believed that cholera was non-contagious.—Dr. J. W. MOORE held that there was an analogy between the contagion and etiology of cholera and of typhoid fever. There could be little doubt, that when the virus of cholera was discharged into gravel-beds, it underwent a process which rendered it fertile and caused it to spread through the neighbourhood. If that were true, the theory of Pettenkofer strongly supported the theory of contagion.—Dr. GRIMSHAW said one of the points assumed in his paper was that cholera was contagious. If it were not contagious, the theory of Pettenkofer could not be valid in any shape. The only theory of contagion with respect to cholera held anywhere was that the discharge from the patient's bowels was capable of reproduction or development, and that the introduction either of the matter discharged or of the product of it into the bodies of other persons propagated the disease. As to the disease following river-courses, it was admitted that it did so in so far as a river afforded means of transit or traffic, like a railroad, an ordinary road, or the sea. That was what was generally meant by cholera following a river-course. The Geological Survey had mapped the gravel-bed of Dublin only within the last twelve months; and, until he (Dr. Grimshaw) asked for the information, the map was not drawn. He had seen the Dublin gravel-beds opened in a great many places, and more particularly in a gigantic way near the King's Bridge by Messrs.

Guinness, in order to obtain lime for their new buildings; and the gravel-stones so obtained were burned and yielded very good lime. It was his intention at a future day to compare the paths of cholera in the country districts with the geological maps, when the Geological Surveys were sufficiently complete for the purpose. It had been shown by the reports of Cunningham and Lewis in India, that those points were of considerable importance. Those gentlemen were still pursuing their inquiries. He believed that Pettenkofer had shown good grounds for his theory, and that it had been very much borne out by their experience in Dublin.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 15TH, 1878.

### THE TWO MEDICAL ACT AMENDMENT BILLS.

"THE Medical Act, 1858, Amendment Bill (No. 2)" is now before the House of Commons, endorsed by Mr. Arthur Mills (Member for Exeter), Mr. Childers, and Mr. Goldney. Mr. Arthur Mills and Mr. Goldney are influential supporters of the Government, while Mr. Childers is second to none in authority in the councils of the Opposition. It is matter of congratulation, and indeed striking evidence of the weight of the Association, that it has been so fortunate as to secure the approval of such supporters; and the profession as well as the members of the Association cannot but feel assured that their interests, in as far as they harmonise with those of the public, will be perfectly safe in their hands. Medical Bill No. 2, launched under their auspices, is removed from the sphere of party, and affords a good opportunity for arranging a compromise with the Government. The promoters are not of those who would obstruct the progress of medical reform, and most decidedly would not lend themselves to any factious opposition.

The measure thus introduced—"Bill No. 2"—was settled by the Medical Reform Committee, in conjunction with the late Mr. Headlam, in 1873, on the principles repeatedly affirmed by the British Medical Association, and provided:

1. Direct representation of the profession in the General Medical Council; and
2. The establishment of a Conjoint Examining Board in each division of the kingdom, under the sanction and supervision of the General Medical Council, as the only portal of admission to the profession, on the principle of equal fees and uniform examination.

The delay which has occurred in pressing forward this Bill has been due to a desire not to embarrass the English medical authorities in their laudable efforts to combine in the formation of a conjoint scheme of examination for their division of the kingdom. Each year in passing, it was supposed the scheme would be completed; and so year after year the Bill of the Association remained simply suspended over hesitating and vacillating corporations. This delay was sanctioned and approved by the British Medical Association at each succeeding annual meeting. It was felt that the success of the English authorities in this respect would strengthen the position of the Association, in compelling the authorities in the two remaining divisions of the kingdom to do likewise.

In 1877, the conjoint scheme in England seemed on the verge of completion, when a resolution to admit women to the degrees of the University of London again jeopardised it. Under these circumstances, the Medical Reform Committee, strengthened by the efforts of the English authorities, which had met with nothing but approval from all quarters, felt that the time had again come for the Association to resume the struggle. The state of the position as regarded medical reform was laid before several members of the legislature, but particularly before Mr. Childers and Mr. Mills. This was done in anticipa-

tion of the assembling of Parliament. The principles embodied in the Bill of the Association had been previously reduced to writing by Mr. Goldney, and received his approval. Regard being had to the difficulties besetting all attempts at legislation where large private, corporate, and public interests are involved, and the impossibility of success attending them when in the hands of private members, it was suggested that the best mode of dealing with so important a subject would be to ask for a Committee of the House upon the whole question, before which a thorough investigation of all the points at issue might be carried out during the present session, preparatory to legislation during the ensuing year. The bases of medical reform being thus settled in Committee, the difficulties inherent to so complicated a subject would be smoothed over, and legislation be comparatively easy and certain. This advice was submitted to the Medical Reform Committee of the Association during a meeting held in London on February 7th, and instructions were then given to the chairman authorising the application for a Select Committee in the manner indicated. During the negotiations which followed, it soon transpired that the Government had already a Bill drafted on the same subject. This information necessarily prevented the intended application for a Committee in the House of Commons.

After no long time, the Bill of the Government was introduced in the House of Lords, and the action of the Medical Reform Committee with respect to it has been recorded. On April 1st, as soon after the introduction of the Bill as possible, a deputation from the Committee had an interview with the Lord President, when the deepest regret was expressed at the utter inefficiency of the manner in which the conjoint scheme was dealt with, and urgent representations were made that so strong a government might well undertake to establish it in all its integrity. The demand for the reform of the General Medical Council was also placed before his Grace as a point insisted on by the great body of the profession.

On May 18th, the Lord President again most courteously received a deputation from the Committee, when the result of the answers received to the queries of the Committee respecting the conjoint scheme and direct representation, addressed to the profession, was laid before his Grace, proving, as far as they went, something like unanimity of the profession on both points. The Lord President on this occasion expressed his consent to concessions to the extent of enforcing conjunction on the corporations in Scotland and in Ireland, but insisted on leaving the universities free. Further than this, his Grace stated he could not go.

Under these circumstances, in consequence of the Lord President's Bill not enforcing the conjunction of the universities with the corporations, and not including direct representation, the Medical Reform Committee decided that the Bill of the Association—"Medical Acts, 1858, Amendment Bill (No. 2)"—should be introduced in the House of Commons, which was accordingly done on May 29th. At the time when the decision was formed, the further concessions of the Lord President, by which the conjoint scheme was enforced alike on the universities and corporations in each division of the kingdom, were not known to the Committee.

In the final passage of the Lord President's Bill through the House of Lords on June 4th, it was still more closely assimilated to the Bill of the Association by the introduction of an important amendment proposed by the Marquis of Ripon.

Clause 4 made it necessary for a person who has passed the joint board examination to obtain a medical diploma from one of the existing medical authorities before he could be placed on the *Medical Register*. The Marquis of Ripon moved an amendment to make such diploma unnecessary for the purposes of registration. This amendment was accepted, and, as a consequence, the examination by the Conjoint Board will be the absolute portal to the profession. It will be no

longer incumbent on anyone entering the profession to be affiliated to any of the corporations. The passing of the examination of one of the conjoint boards will entitle the candidate to be placed on the *Medical Register* a regularly qualified medical practitioner. There can be no doubt that the great majority of medical men will be content with this qualification, and, as a consequence, the mass of the profession, having passed the testing ordeal of an examination in all branches of their art, will be unconnected with any of the colleges. As regards the Apothecaries' Society of London, it has played its highly useful part; few will in the future seek to be enrolled amongst its licentiates, and it seems not unlikely to become little more than a trading company. The same must be the case with the Apothecaries' Hall of Ireland: both are apparently destined to speedy extinction as medical authorities, though both, under the present constitution of the Medical Council, will still have their representatives in it.

We will not dilate at greater length on this distasteful theme. Sufficient hints have been thrown out to indicate the retribution for opportunities lost, which is likely to fall on corporations which neglected to avail themselves of the opportunities afforded them, since the Medical Act of 1858, to shape the medical education of the country by treating the question of medical reform on a broad basis, and not with an eye to the narrow and selfish interests of individual corporations.

The destruction looming in the future as the probable fate of some of the corporations will doubtless stir up an opposition to the Lord President's Bill, which it will not be easy to master. The Scotch and the Irish corporations are fully alive to their perilous position, and exercise a far greater influence in the House of Commons than even the Royal College of Surgeons with its 13,000 members and 700 fellows. There are, however, other matters which demand careful consideration. It is unfortunate that the Bill underwent no discussion worthy of the name in the House of Lords. The admission of women to the ranks of the profession, which, whether reasonably or unreasonably, caused such commotion in the ranks of the profession that the presence of two educated ladies in the Association caused the secession of more than one distinguished member, passed in the House of Lords without a murmur. The granting of privileges in the way of registration to the possessors of foreign and colonial degrees, which are not accorded to the degrees of the best of our own universities, did not even excite observation. When the Marquis of Ripon's amendments were accepted, and it became clear that the rank and file of the profession would, in consequence, have no connection with any corporation, the question of discipline as regards them was not once considered. Again, there is a very remarkable circumstance which has not received the attention it merits. The coveted distinction of the title of Doctor is one that perhaps more than any other attracts the general practitioner; and it is not at all impossible that, under the state of things which the Lord President's Bill would create, the Queen's University of Ireland, notwithstanding the determined hostility of its representative to the conjoint scheme, may yet find its advantage in the demand for a doctorate awarded on cheaper terms than by any other university.

The absence of discussion on these and other points leaves much to be done in the Commons. Amendments are inevitable; their discussion demands time, and time is wanting. Had the Medical Council numbered in its ranks the proportion of direct representatives which the profession seeks to infuse into it, these questions would have received the consideration they demand, and the difficulties they present would have been solved. So diffident is the Council as to the questions it should discuss, owing probably to the nature of its component parts, that it is positively afraid to undertake the additional duties imposed by the Lord President's Bill.

Clause 14 provides that the Medical Council *shall* make examination-rules for "regulating the examinations" of persons desiring to obtain qualifications within the meaning of the Act.

The Medical Council remark on this clause—"That the duties of the Medical Council, in relation to the various medical authorities (whether in separate or in joint action), should not be extended to the initiation of the examination-rules under which qualifications are to be granted, but should in general be restricted, as now, to duties of superintendence and control, with power of making representation to the Privy Council in cases of default."

The duties and power referred to in the above observation are conferred by Section xx of the Medical Act of 1858, which provides that the Medical Council may report defects in education and examination to the Privy Council; and Clause xxi provides that the Privy Council may suspend the right of registration of the diplomas issued by the body whose curriculum or examinations the Medical Council has complained of.

The Association is irrevocably pledged to direct representation, and the consequent strengthening of the General Medical Council in the estimation of the profession. With this view, Medical Bill No. 2 was introduced, as well as to realise the conjoint scheme. Medical Bill No. 2, as was stated in the interview with the Medical Council, is open to amendment. Unfortunately, the Lord President would not concede direct representation: had he done so, the undivided weight of the Association would probably have been exerted in his behalf; but, even then, amendments in the Government Bill would have been inevitable. As it is, both Bills will be before the legislature. In this manner, a compromise may possibly be arranged, or both Bills may be referred to a Select Committee, and thus a more carefully considered and more thoroughly matured measure than either may be the result, and become law in the ensuing year.

#### THE GLYCOGENIC FUNCTION OF THE LIVER.

THE fate of the hepatic glycogen is one of the most disputed points of physiology. Is it a reserve store of carbo-hydrate material? Is it converted directly into fat? Does a reconversion of glycogen into sugar occur during life? To one and all of these questions very conflicting answers have been given. We have Bernard and his supporters, on the one hand, affirming that normally the liver, continually or at intervals, is changing its glycogen into sugar, and discharging it into the hepatic veins; Pavy and his followers, on the other hand, asserting that during life, under ordinary circumstances, there is little or no difference in the amount of sugar contained in the portal and hepatic venous blood, and therefore no conversion of glycogen into sugar at all.

We shall not here discuss the question of the direct change of glycogen into fat, as it is now considered on good authority that albumen is the chief, if not the only source of the fat in the body, except, of course, that derived from the fat ingested as such; but confine our attention entirely to the primary and more important question as to whether or not there is reliable evidence that glycogen is changed into sugar, normally and during life. This resolves itself into whether the blood of the hepatic vein contains or does not contain in life more sugar than that of the portal vein. Bernard takes the affirmative, Pavy the negative. Both have comparatively recently contributed the latest results of their experiments. Bernard to the French Academy of Sciences, and Pavy to the Royal Society. As they have arrived at their conclusions by employing different methods, we must examine these in detail, sketching briefly, at the same time, the results themselves.

Bernard's latest conclusions may be thus summed up. The existence of sugar in the blood is not an accident dependent on the food, but a physiological phenomenon as constant and permanent in the organism as all the other phenomena of nutrition, of which, indeed, it is a direct expression. Whatever the nature of the food, in herbivora as well as in

carnivora, during digestion, during abstinence, even during fever, the blood always contains nearly the same proportion of sugar; and there exists in the living organism a glycogenic function which maintains and regulates this proportion, thus rendering it independent of the variable conditions of digestion. In the arterial system, the proportion is sensibly equal everywhere; but in the venous system it is variable, and always inferior to that of the arterial blood, the only exception being in the hepatic veins, the blood of which is richer in sugar. The amount in the arteries varies between 1 *gramme* and 1.5 per 1,000, between .06 and .08 in the vena portæ, and between 3 and 7 *grammes* in the hepatic vein. An augmentation occurs every time the animal is bled; which cannot be explained by the condition of alimentation, for it supervenes in dogs when starving or when fed with meat. The blood is therefore deprived of sugar in its passage through the organs of the body, but is enriched again by traversing the liver. To avoid the state of local superactivity in the circulation and absorption of fluids produced by the opening of a vessel in the living animal, Bernard generally draws the blood from a large vessel by means of a catheter, the vessel being ligatured so that the movement of the blood at the point operated upon is neither notably accelerated nor retarded. By this mode of catheterisation, either from above by the right jugular vein, or from below by the femoral vein, the hepatic blood is extracted. By operating in this way, it can be shown that the superior cava is poor in sugar; and that the inferior cava in the pelvis contains less sugar than the corresponding arterial blood, less also at the level of the renal veins, but is suddenly enriched at the liver by the entrance of the hepatic blood. As this blood, rich in sugar, is mixed with the blood of the inferior and superior cavæ, which is poor in sugar, there results a dilution that leads to the proportion of sugar in the right ventricle approaching closely that of the blood in the left ventricle, thus showing that there is a less sensible destruction of sugar in the pulmonary than in the systemic capillaries.

So much for Bernard's results. Now for his method of quantitative analysis. The blood is received in a tared capsule, accurately weighed; an equal weight of sulphate of soda in small crystals is added to it, as well as a few drops of acetic acid; it is boiled briskly, stirred, and expressed hot, the loss of weight by evaporation being made good by adding water. The filtrate, which contains the sugar, is then titrated with Fehling's solution; but, on account of the small amount of sugar present, only one cubic *centimètre* of Fehling's solution, with twenty to twenty-five cubic *centimètres* of concentrated solution of potash added, is acted upon.

Bernard has assured himself that in blood so treated by sodic sulphate there exists no substance other than sugar which can reduce the cupric oxide; and, by a method of control, he has shown that both his proceeding and the formula used by him give a great exactitude (close upon 1-100,000th). All the analyses must be made as soon as possible, as sugar disappears rapidly from the blood after death: if the death be sudden, from ten to twelve hours are required; if slow, with a gradual destruction of the glycogenic function, fifteen minutes may suffice.

In his communication to the Royal Society, Dr. Pavy points out that the very rapid changes which take place in blood under altered conditions of the system render it essentially necessary that the greatest precaution should be observed in order to obtain blood in its natural condition. If the blood be taken from the living animal, the latter must be perfectly tranquil, as violent muscular action or embarrassment of the respiration will occasion a conversion in the liver of glycogen into sugar; and it should be procured as instantaneously as possible after the death of the animal, so as to be unaffected by the *post mortem* production of sugar that occurs in the liver. He concludes from his experiments that the amount of sugar contained in the blood of sheep and bullocks is about 0.5 per 1,000, and in dogs 0.75 per 1,000, showing a remarkable uniformity in the amount of sugar contained in the respec-

tive animals. No material difference, he maintains, exists between the amount of sugar contained in arterial and in venous blood. As one of the effects of anæsthetics on animals is to occasion an abnormal amount of sugar in the blood, to attain accuracy the blood must be taken when the animal is not under their influence. The blood of a dog killed by pithing gave—carotid artery, .795 (in 1,000); jugular vein, .792. In another animal, the vessels were exposed under chloroform, and, when the effects of the anæsthetic had passed off, the exposed vessels were drawn forward and opened: (1) carotid artery, .811, jugular vein, .798; (2) carotid artery, .863, jugular vein, .879. It is also held by Pavy that the blood in the hepatic veins, if care be taken to keep the animal in a perfectly normal condition, contains no more sugar than does the blood of the right auricle or of the portal vein; in his present communication, however, he makes no fresh reference to this subject.

Dr. Pavy has obtained his results by means of a new gravimetric process of analysis, in which he adopts the use of a galvanic battery for effecting the deposition in a weighable form of the copper that has been reduced by the sugar. [A somewhat similar process was previously followed by Abeles.] This is his method. A certain volume of blood, about twenty cubic *centimètres*, is taken, accurately weighed, mixed with twice its weight of sodic sulphate, thirty cubic *centimètres* of hot concentrated solution of sodic sulphate added, and the whole heated till a coagulum is formed; filtration is then performed, and the clot washed to remove all traces of sugar. The filtrate must be boiled and refiltered to remove the turbidity, again boiled, and, after the addition of ten cubic *centimètres* or more of Fehling's solution, so as to have the copper salt in excess, kept boiling for at least a minute. The resulting suboxide of copper is next separated by filtration through glass wool, washed from excess of copper salt, and dissolved in a few drops of nitric acid. A mercury bichromate battery is now brought into operation, the positive pole of which is formed by a platinum spiral coil; around this, and forming the negative pole, is a cylinder of platinum foil, and upon it the copper is slowly deposited in a pure metallic state, a period of about twenty-four hours being required. Before weighing the platinum cylinder, it is first washed in distilled water, then in alcohol, and finally dried. The increase in weight of the cylinder gives the copper. Five atoms of cupric oxide are reduced by one atom of glucose; therefore 317 copper represent the equivalent of one part of glucose, or 1 copper = 0.5678 glucose: that is, weight of copper  $\times$  .5678 = weight of sugar.

Thus far Pavy. His results, we see, are opposed to those of Bernard. What are we to say when the testimonies are so conflicting? In case the same methods had been employed by both, we should be guided by what we may call the "authority" of the experimenter; and, as a physiologist and experimentalist of standing and repute, we should be forced to give the precedence to Bernard. But the methods are not alike; and Dr. Pavy alleges that his gravimetric process of the electrolytic separation of copper is far more reliable and more accurate than the volumetric one adopted by Bernard. Moreover, he states that Bernard's entire system is based on errors. We confess our inability to see that Pavy has offered sufficient proof of this. Pavy follows almost the same proceeding as Bernard for the separation of the sugar from the blood, and the reduction of the copper, except that he does not employ an excess of caustic potash. He adds, it is true, more sodic sulphate, and an excess of copper salt. Bernard finds the amount of suboxide by a volumetric process; Pavy, by electrolytically separating the reduced copper on platinum and weighing it: here, it seems to us, the chief difference lies. Now, that the excess of caustic potash added by Bernard should vitiate his whole process, would require more proof than Pavy has offered. That it has not prevented the deposition of the suboxide is shown, we think, by Bernard's numbers always being higher than Pavy's. On the other hand, we know that in Trommer's test an excess of cupric salt interferes materially

with the reduction of the copper to the state of suboxide, which, however, is not hindered in any way if the excess be on the side of the caustic potash. We certainly agree with Pavy that exception may be taken to Bernard's assumption as to the relation between the weight of the mixture of sulphate of soda and blood and the volume of liquid obtained; but this assumption has introduced no serious error, for, in his method of control, Bernard added known quantities of sugar to samples of blood in which the amount of sugar present had been previously ascertained, and he found almost exactly the amounts added, as the following numbers prove: (1) by calculation, 1.26 sugar per 1,000, found by experiment, 1.23; (2) by calculation, 1.10, by experiment, 1.10; (3) by calculation, 1.58, by experiment, 1.56. Such a degree of accuracy is hardly consistent with "an entire system based on errors". Dr. Pavy directs attention to the greater uniformity of his results when compared with Bernard's. This must be granted him; but, at the same time, it may be observed that a considerable discrepancy exists among his numbers also. In bullocks' blood, the sugar varied from .456 to .703; in sheep it was as low as .470; in dogs as high as .921. In two bullocks, the sugar varied from 1.033 to 1.094; but here Dr. Pavy says he had reason to believe some little time had elapsed between the felling of the bullocks and the opening of the vessels. Again, his results on the disappearance of sugar from the blood after death show that in *one* hour the proportion disappearing varied from .015 to four times that amount (in 1,000).

The reduced suboxide of copper has a great tendency to become re-oxidised; and it is very likely that, unless the filtering and washing be commenced at once and executed expeditiously, a certain loss will occur. Dr. Pavy's process is certainly a beautiful one; and, although we do not think with him that there is much room for error of judgment with a practised chemist in determining the final stage of the volumetric process, yet we agree with him that, once all sources of error are eliminated from his method, it will be decidedly preferable in point of accuracy; but the same result might be arrived at by a less complicated process. We have obtained most exactly the quantity of copper contained in a cupric salt of that metal by supersaturating the solution of the salt with ammonia and immersing in it an exactly weighed blade of pure copper. A wide-necked flask, well-stoppered, is used, which is filled up with boiled water and immediately closed after the introduction of the blade of copper. When the quantity of copper is small, a day or two will suffice for the complete decolorisation of the liquor, in consequence of the reduction of the cupric salt into the cuprous condition. The blade is then weighed, after having been washed and dried. From its loss of weight, the amount of copper that existed in the solution can readily be calculated, since cuprous oxide contains twice as much copper as cupric oxide. We suggest this simple and easy method to Dr. Pavy's notice.

In the last number of Pfliiger's *Archiv für Physiologie*, there is a paper by Professor Worm Müller on the titration of grape-sugar, in which he very strongly advocates Knapp's process, which consists in the reduction of mercuric cyanide. The chief difficulty in Fehling's test certainly lies in determining sharply the termination of the reaction; and whether this be judged of by the loss of colour, or by testing a portion of the fluid after filtration with potassic ferrocyanide, there is always a tendency to error unless in practised hands. Now, in Knapp's process, according to Professor Müller, in addition to the terminal reaction being capable of exact determination, there are also these advantages: the test-fluid is easy to prepare, is not liable to alteration by keeping, and is much more accurate and delicate than Fehling's solution, as it gives indications of sugar in fluids where it has been undetected by this solution; the mercury also, when once reduced, is not redissolved, as is the case with the reduced suboxide of copper.

All these processes, however, as Professor W. Müller himself points

out, are founded upon the reducing action exerted by sugar on certain metallic salts. But this action is not proper to sugar alone, as it is also possessed by certain other organic bodies existing in animal fluids. Moreover, there is reason to believe that there are other bodies present in the blood besides albumen, capable of hindering this reducing action. In Bernard's process, the albumen is removed, but the other bodies may still remain. When the determinations concern decimal percentages, every source of error must be taken into consideration and eliminated, otherwise the results can only at best be regarded as comparative. A quotation here from Professor Worm Müller's article will not be out of place. "Urine not only contains bodies that reduce cupric oxide, but also others that hinder its precipitation, so that part of it may pass through the filter as finely divided or dissolved cupric hydrate. Every brain, lung, or muscle extract of a diabetic patient contains a large proportion of such substances; consequently, it is very probable that animal fluids, such as blood and chyle, even when deprived of their albumen, usually contain substances of a similar kind." With regard to Pavy's process, he goes on to say he feels assured that the precipitate collected on the glass-wool filter does not represent the whole of the reduced oxide; and that to attain accuracy by the method is impossible, inasmuch as Fehling's solution being added in excess, the filtrate must contain copper. "In other words, from the physiological standpoint, this modification of Fehling's method can in no respect be regarded as possessing any real advantage whatever in point of accuracy."

In every case, therefore, the possibility of other reducing agents besides sugar being present must be borne in mind. It is not enough to get phenomena of decoloration or reduction. We must assure ourselves of the character of the body producing the changes. What is wanted is the power to isolate the sugar, and differentially distinguish it; if we cannot isolate it, let us at least make sure of its presence.

After all, however, even should we accept Dr. Pavy's figures, it does not follow, because his experiments indicate no material difference in the amount of sugar in venous and arterial blood, that no such difference exists. This difference might be so slight as to fall within the limits of the errors of experiment; and yet, when the rapidity of the circulation is taken into account, it is easy to see that over a comparatively short period of time great additions and subtractions might occur in the circulating fluid which were incapable of being recognised at any given moment by the means at our present disposal.

Notwithstanding, therefore, our respect for Dr. Pavy—and the good work he has done entitles him to be heard with attention—we still hold by the old opinion advocated by Bernard. It has not yet been clearly disproved, and till it is it shall form part of our physiological faith. There is every reason, we think, for believing that a certain percentage of sugar is necessary for the maintenance of the average composition of the blood; and it is not an unnatural assumption that most of the tissues remove some of it for their nutrition, and that this constant demand is supplied by a conversion of the glycogen stored up in the liver, a store upon which the organism can always make a call when the need for it arises. And this assumption does not bind us to maintain that all the hepatic glycogen is thus disposed of.

---

THE President and Fellows of the Royal College of Physicians of London have issued cards for a *conferentia* on Wednesday evening, July 3rd, at nine o'clock.

---

It is intended, we learn, with the assent of Mr. Erasmus Wilson, to widen the scope of his professorial endowment of the College of Surgeons, which he at first limited to dermatology, and of which he was the first incumbent. In future, it is proposed, that a wider range of surgery and pathology be included within the selection of subjects.

DR. BURDON SANDERSON will deliver the Harveian Oration at the Royal College of Physicians at five o'clock, on Wednesday, June 26th.

A CAREFUL series of experiments on *Drosera Rotundifolia* by Mr. F. Darwin and two German observers, reported in *Nature* (June 6th), have no doubt that *drosera* plants profit largely by an animal diet.

IN the Russian army in the neighbourhood of Constantinople, 25,000 men are down with typhoid, typhus, and other diseases. Heavy rains fell last week. The heat is great, and a further increase of sickness is expected.

PROFESSOR H. C. WOOD, junior, has, according to the *New York Hospital Gazette*, analysed the seeds of *Sophora Speciosa*, a native plant of Texas, and has detected a new alkaloid, which he names *Sophoria*. Half of one of the seeds is said to be sufficient to produce delicious exhilaration, followed by a sleep lasting one or two days.

PROFESSOR AND MRS. FLOWER received a large party of friends in the splendid museum of the College of Surgeons, Lincoln's Inn Fields, on Saturday afternoon, to meet the Chinese Minister. Mr. Flower loses no opportunity of inviting London celebrities, and the flower of the scientifically minded members of London society to visit this splendid collection; and his social courtesies have done much to reinforce the scientific labours by which he has added lustre and popularity to the Hunterian Museum.

I. VON LENHOSSÉK has, it is reported, constructed an apparatus which permits no fewer than sixty microscopical preparations to be observed in immediate succession, without the trouble of changing the slides and readjustment of the object-glass. Its construction is similar in principle to that of the well-known revolving stereoscope. The inventor has given the new apparatus the name of "polymicroscope".

MR. SPENCER WELLS commenced his course of lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours, in the theatre of the Royal College of Surgeons on Monday last, and will bring the same to a close on Friday, the 21st inst. He will be succeeded on the 24th inst. by Mr. B. T. Lowne, F.R.C.S., who will deliver three lectures on the Physiology of Nerve-Stimulation. After this, the annual and interesting exhibition of preparations, etc., about to be added to the museum, will take place, but must be closed on July 5th (immediately after the annual election of Fellows into the Council) in order to carry on the primary examinations for the diploma of membership.

MM. BOCHEFFONTAINE and Tiriakin, in investigating the physiological properties of conine, have arrived, according to *Nature* (to whose valuable notes of foreign societies we are often much indebted) at the following conclusions. Conine pure, or bromhydrate of conine, is not a very formidable poison, and not to be compared with hydrocyanic acid (as has been supposed). Sixty-five centigrammes of pure conine, introduced under the skin of a dog weighing seven kilograms, killed it in a little over twelve hours; fifty centigrammes sufficed for a similar dog when introduced into the stomach. The chlorhydrate and bromhydrate are always more active than the pure conine. M. Mourat has separated from the conine furnished as pure in shops a resinoid matter, which, like curare, paralyzes the motor nerves.

MR. G. JACKSON of Plymouth recalls attention to a subject formerly much discussed, that of voting by proxy at the election of members of Council of the College of Surgeons. It was, at one time, a sort of battle-cry at College-elections. It might be advisable that this question should be thoroughly ventilated in an official manner, either by provincial or other members of the Council. It is obvious that at present a large proportion of the Fellows are practically disfranchised by their distance from the place of election.

M. VULPIAN reported to the Académie des Sciences on May 27th some researches on the action of anesthetics on the respiratory centre and cardiac ganglia. In chloralised dogs, faradisation of the upper cephalic segments of the cut vagi stops the respiratory movements just as in dogs not anesthetised; but whereas, in the latter, the respiration in general easily and spontaneously commences again, in spite of the electrification being continued, it is not so with the former, and the animals die unless electrification be stopped and artificial respiration be precluded, aided, it may be, by energetic faradisation of the trunk. The heart, too, may finally stop in such a case. M. Vulpian thinks this explains certain accidents in clinical anaesthesia.

M. CHARPENTIER, reporting to the same learned body on the production of the luminous sensation, states that where we find less red substance in the retina we observe a less luminous sensibility, and wherever the red appears in excess this sensibility is exaggerated. It is concluded that the luminous sensibility, defined as the simple and original reaction of the visual apparatus to all luminous excitations of whatever nature, is in relation to the degree of photo-chemical action exercised on the red of the retina by all the luminous rays.

THE *Pharmaceutical Journal* of June 1st contains a very long *verbatim* report of the case "The Society of Apothecaries v. Wiggan", to which we last week referred, in which the Medical Alliance Association, originated by Mr. R. H. S. Carpenter, recovered multiple penalties against a chemist for practising medicine. The report occupies nearly the whole of the space of that journal, and thus evidence is afforded of the importance attached to the question by the general body of dispensing chemists. The result, as we have stated, was eminently satisfactory. There are some special features of interest in the elaborate summing up of Mr. Justice Field; but the whole report is well worth reading. It was admitted on all hands that the chemist and druggist is expressly excluded from acting in the character of an apothecary.

ON the question, What is an apothecary? which governs the whole of these cases, Mr. Justice Field laid down the law as follows.

"Now, I have before me the definition of an apothecary, as I find it laid down by those who have gone before me. 'I should tell you that the duty of an apothecary is, that he is a person who professes to judge of internal disease' (but internal here merely means as distinguished from surgical; it is not intended to mean one particular part of the body)—to distinguish ailments such as fevers. It would be difficult to find one word which expresses it all; but you know the meaning of that, 'to judge of internal disease by its symptoms, and applies himself to cure the disease by medicine'. That is the definition laid down by a very learned judge, Mr. Justice Cresswell, in a case he left to the jury as far back as 1845; and I adopt that, and tell you that is the law. I take his language, adopt that language, and tell you that a person practises as an apothecary if he does what Mr. Justice Cresswell here says: if he professes to judge of internal disease by its symptoms, and applies himself to cure that disease by medicines. I should ask you to keep that definition in your minds when I come to read you the evidence, and to see whether or not what the defendant did here falls within that. Then I find another definition some years before, in which the learned Lord Chief Justice of the Queen's Bench of that day was of opinion that a man who kept no shop, but advised patients and made up and sold to them medicines which he himself ordered, did act as an apothecary in the ordinary sense of the term; and that it made no difference if he prescribed as well as prepared the medicines; he was still acting as an apothecary. I give you these two decisions of two very learned judges, and I adopt them as the law which I lay down to you to-day."

THE Apothecaries' Society must feel rather uncomfortable under the censure implied in the ill-founded compliments addressed to them by their counsel, Mr. Morgan Howard, Q.C. "I am sure," he said, "you will think that the Apothecaries' Company are only doing their duty, which they are bound to discharge for the protection of society, in bringing this matter before you for your determination to-day." The fact is, that the Apothecaries' Company have entirely neglected their

duty to society and the profession in this matter. They have done nothing to protect the poor from the abuse now pointed out, or the profession and their licentiates from the encroachment on their privileges. So long continued, so systematic have been this abuse and the neglect on the part of the Apothecaries' Company to define and to enforce the rights of which they are the legal depositaries and representatives, that the judge in this case very naturally and fairly prefaced his summing up by observing to the jury that "the defendant was not to blame in any way; no doubt he has done that which he for many years and a great many other respectable people have been in the habit of doing". Moreover, although these proceedings are taken in the name of the Apothecaries' Society, *stat nominis umbra*, they are represented only by the shadow of their name. The expenses, trouble, and responsibility of the score of proceedings which have been so successfully adopted have rested wholly upon a few private general practitioners, who, without any public position or official responsibility, have combined to fight a public question of great magnitude and importance, foremost amongst whom must always be mentioned Mr. R. H. S. Carpenter, Mr. G. Brown, and Mr. Nelson Hardy. It was with the greatest difficulty that they succeeded in rescuing from the hands of the Apothecaries' Society the penalties recovered in the first cases.

ANOTHER member of the "Peculiar People" sect has been committed for manslaughter, on the charge of having omitted to procure medical advice for an infant, whose death was by this neglect accelerated.

#### THE DEATH OF MR. EDWARD SPENDER.

THE lamentable death of Mr. Edward Spender and his sons by drowning at Whitsand Bay should quicken the sense of responsibility of those who have any authority in the charge of such dangerous shores. It appears that this is a locally well-known quicksand, where bathing is dangerous. That knowledge visitors cannot be expected to share; and Caution Boards in such places may save valuable lives. Mr. Spender's was a valuable life. He had done good work in many a cause of local reform, notably in that of temperance. The Phoenix Coffee Tavern in the Harrow Road was started by him; and he was working for good ends up to the day of his death. Only three days before that sad event, we had personally communications and help from him towards extending the coffee-tavern movement in the neighbourhood of King's Cross. Modest, sincere, gentle-hearted, and quietly but resolutely energetic in good social work, he has left among his friends the affectionate and respectful memory of a very noble nature and very sincere striving for usefulness to his fellows.

#### THE BRISTOL MEDICAL SCHOOL.

AT a meeting of the Council of the Royal College of Surgeons of England on Thursday last, the following motion was carried: "That, as recommended by the Court of Examiners, for the present the recognition by this College of the Bristol Medical School be not withdrawn, in the expectation that the proposed improvements of the arrangements for teaching in that School will be carried out, and on the understanding that a report will be furnished by the Honorary Secretaries of the School at the end of the winter session 1878-79, respecting the progress which shall have then been made in effecting those improvements."

#### INSANITY BEFORE THE COURTS.

THE Criminal Code Bill, now before Parliament, proposes to deal, among other important subjects, with the acknowledged defects of the law at present in respect to the legal definitions of insanity, and the responsibility of persons of unsound mind. This it does in accordance with principles laid down by Sir J. Fitzjames Stephen. The proposed enactment is as follows:

"No act shall be an offence if the person who does it is at the time when it is done prevented, either by defective mental power or by any

disease affecting his mind, (a) from knowing the nature of his act; or (b) from knowing either that the act is forbidden by law or that it is morally wrong; or (c) if such person was at the time when the act was done, by reason of any such cause as aforesaid, in such a state that he would not have been prevented from doing that act by knowing that if he did do it the greatest punishment permitted by law for such an offence would be instantly inflicted upon him, provided that this provision shall not apply to any person in whom such a state of mind has been produced by his own default. An act may be an offence although the mind of the person who does it is affected by disease or is deficient in power, if such disease or deficiency does not in fact produce one or other of the effects above mentioned in reference to that act."

It would be interesting to hear the opinions of some of our leading alienist physicians and medical jurists upon this section, which has been drawn by one of the ablest jurists and most competent in such matters.

#### A MUSEUM OF HYGIENE.

THE Clothworkers' Company have contributed a sum of twenty guineas towards the sustentation fund of the hygienic museum founded in memory of Dr. Parkes at University College. At a meeting of the subscribers to the Parkes Memorial Fund lately held at University College, Sir William Jenner, Dr. Sieveking, and Dr. Poore were appointed trustees to the fund; and we believe it is intended to invest £600 to form a nucleus for the adequate endowment of the museum, without which its permanent success is obviously impossible. A museum is necessarily a thing of gradual growth; but already the Parkes Museum is becoming worthy of the name. The food collection, which has been enriched by many contributions from South Kensington, Kew, and the private collection of Thomas Twining, Esq., has already assumed considerable proportions; and the War Office and Admiralty have sent many articles illustrative of naval and military hygiene. The library already contains between three and four hundred volumes of books on sanitary subjects, and the executive committee are striving to make the museum a centre of information for all matters connected with hygiene in its widest sense. It is, we believe, in contemplation to exhibit a fully equipped field-ambulance, which would at the present time be highly instructive. All persons interested in hygiene will be welcome to the museum, which is intended to benefit not one school alone, but the public at large.

#### A REFORMER IN THE TREATMENT OF LUNACY.

WE have to record with regret the death of Dr. Robert Gardiner Hill, whose name will always be identified with the abolition of those rougher and more barbarous methods of treatment of lunatics which prevailed till the beginning of the present century, when medical research prevailed over bequathed monkish and metaphysical error, and the lunatic was recognised as a person the subject of physical brain-disease, and requiring medical treatment rather than cruel restraint, stripes, and chains. Dr. Hill took an early and prominent part in the abolition of mechanical restraint in the treatment of lunatics, and in 1851 he received a public testimonial in recognition of his distinguished services in this humane and enlightened work. He was one of the first to recognise that, in the management of insanity, to quote his own words, "moral treatment was all and everything". So early as 1836, he advocated the disuse of instruments of restraint; and in the following year, in the Report of the Lincoln Asylum, he asserted his belief, which was based upon his own practical experience, that an asylum for the insane might be conducted "without having recourse to the employment of any instruments of restraint whatsoever". It was not till 1839 that Dr. Conolly undertook the management of Hanwell Asylum and finally abolished the employment there of mechanical restraint for lunatics. In his early days, Dr. Hill contributed largely to contemporary psychological literature. Amongst other writings, he published *A Concise History of the Entire Abolition of Mechanical Restraint in Treatment of the Insane*. He was much esteemed by a wide circle of professional friends, and he earned a very large amount of success as a practitioner.

## PHYSIOLOGICAL PHYSICS.

THE following passage from the Rede Lecture delivered by Professor Clerk Maxwell lately at Cambridge is, we think, of especial interest, as indicating the applications which our physiologists are likely to make of such instruments as the telephone, phonograph, and microphone, in a line of research which may prove ultimately not less valuable to practical medicine than to the physiological institutes of medicine.

"Among all the recent steps in the progress of science, I know none of which the truly scientific or science-producing consequences are likely to be so influential as the rise of a school of physiologists who investigate the conditions of our sensations by producing on the external senses impressions the physical conditions of which can be measured with precision, and then recording the verdict of consciousness as to the similarity or difference of the resulting sensations. Professor Helmholtz, in his recent address as Rector of the University of Berlin, lays great stress on that personal interaction between living minds which I have already spoken of as essential to the life of an university. 'I appreciate', he says, 'at its full value this last advantage, when, looking back, I recall my student-days and the impression made upon us by a man like Johannes Müller the physiologist. When one finds himself in contact with a man of the first order, the entire scale of one's intellectual conceptions is modified for life. Contact with such a man is, perhaps, the most interesting thing life may have to offer.' Now, the form in which Johannes Müller stated what we may regard as the germ which fertilised the physiology of the senses is this, that the difference in the sensations due to different senses does not depend upon the actions which excite them, but upon the various nervous arrangements which receive them."

## THE SUCCOUR OF THE WOUNDED.

THE Women's Society for Succouring the Sick and Wounded, established in Germany under the protection and patronage of the Empress Augusta, recently held its second meeting in Dresden. The assembly was attended by one hundred and seventy-one delegates, of whom one hundred and twenty-four were ladies and forty-seven gentlemen, from Dresden, Berlin, Leipzig, Magdeburg, Würzburg, and other German towns; and also by the Empress herself and by the Queen of Saxony, the founder of the Albert Society established in Dresden. A paper was read on the occasion by the surgeon-general of the Saxon Army Corps, on the working of voluntary societies for tending the sick, in which it was mentioned that during the Franco-German war of 1870-71, 54,000,000 marks were spent by these societies, and that 149,000 sick and wounded passed through the station at Nancy. An account was then given of the work done during the late Turco-Russian war, in Constantinople and Bucharest, by the members of the Saxon Albert Society; the speaker declaring, according to the report of the proceedings, with much animation and eloquence, that it was thanks to the kindly zeal, untiring energy, and careful forethought of Her Majesty Queen Carolä that it had been possible for the Society to carry out its Christian and philanthropic work on the shores of the distant Bosphorus. At the close of the proceedings, the Empress, in the name of the German Society, thanked the Queen for the invitation to meet at Dresden, and for the interest she had manifested in its welfare.

## CONTROL OF DIPSOMANIACS.

THE first Annual Report of the Society for Promoting Legislation for the Control and Cure of Habitual Drunkards shows excellent progress in a short space of time. The society has been actively and influentially supported, and has a goodly list of vice-presidents, as well as an active executive committee. Its treasurer is Dr. Alfred Carpenter of Croydon, and its honorary secretary Mr. Stephen S. Alford, two members of our Association (members of the Committee on the Cure and Treatment of Habitual Drunkards), whose earnestness in this cause is well known. The society was only organised in September last, Dr. A. Carpenter in the chair. Already they are able to report that, taking for their guidance the Report of the Committee of the House of Commons (1872) on Habitual Drunkards, the late Mr. Donald Dalrymple's Bill founded on that report, and the various Acts

already in operation in America and Australia, after considerable labour and expense, with the assistance of counsel, a Bill has been framed. Provision is made in this measure for receiving habitual drunkards into retreats, upon request, to be attested by a justice of the peace or a commissioner for affidavits; or upon an order of justices on the application of friends in a proper case. A Bill with such provision was introduced by Dr. Cameron, M.P., last session, but too late for the second reading. This year, Dr. Cameron has again introduced a Bill, and has secured July 3rd for the second reading. It is the first on the list for that day. The Committee hopes that all interested in this important question will do their utmost to urge upon all members of Parliament within their influence the necessity for such legislation. Petitions have been presented to both Houses of Parliament in favour of this legislation; namely, eighty-five to the House of Lords, containing 5,512 signatures; and one hundred and three to the House of Commons, containing 7,008 signatures, including numerous church dignitaries, medical men, jail authorities, clergy, and members of various temperance societies. Petitions have also been presented by other bodies. In the House of Commons, such a measure will find much sympathy; such, indeed, as it must fairly claim from all enlightened persons, and especially from those who know how largely the jails are filled with habitual drunkards, as well as the workhouses and hospitals. We must expect also to hear "the liberty of the subject" paraded against any and every such measure; but, if some middle way can be found in this Bill to help us in arresting the downward course of the habitual drunkard, without shocking the lawyers too much, it would be a most beneficent and quite invaluable legislative enactment.

## SCOTLAND.

ON Saturday last, the premises of the Glasgow Apothecaries' Company were almost entirely destroyed by fire. The loss is estimated to reach nearly £30,000, the greater part of which is covered by insurance. The cause of the fire has not been made out.

THE annual report of the Dundee Royal Infirmary has just been issued. During the past year, 1,686 patients were treated, being 112 more than in the previous year. Of these, 1,412 recovered or were relieved, 134 died, and 140 remained under treatment.

A SHOCK of earthquake was felt at Comrie in Perthshire, at half-past four o'clock on Sunday morning; it was accompanied by a loud report, described by one of the inhabitants "as if two very powerful pieces of ordnance had been discharged far under ground". The shock was the most severe experienced for many years, and was felt all over the upper valley of the Earn, from Lochearnside on the west to within a few miles of Crieff. The vibration, as usual, came from the south-west, and proceeded in a north-easterly direction. It is noteworthy that the shocks came, as has frequently been noticed on former occasions, after two or three days of incessant rain.

## DRAINAGE OF NAIRN.

THE Nairn Police Commissioners have resolved to submit to the Board of Supervision for consideration the drainage and irrigation scheme prepared by their engineer, and to ascertain whether the Board is willing to recommend the Loan Commissioners to grant a loan of £60,000 and also a sum of £3,600 to complete and extend the works.

## SCIENCE AS APPLIED TO AGRICULTURE.

SIX months ago, the Highland and Agricultural Society determined to try some experiments as to the effects of different substances applied in the form of manure to growing crops. In his report giving account of the work being carried on at the experimental stations, the Society's chemist, Dr. Aitken, says: "The manures have been made up with the utmost care, and applied to the soil with great precision, the seed

has been sown, and, under favourable circumstances, will be branding in a few days. The crop at both stations is for this season turnips. The general character of the experiments is easily comprehended. It is a series of about forty experiments to determine how far the *form* in which a manure is applied affects its efficacy as a crop-producer. Of the forty rood-plots into which each station is divided, thirty-five are taken up with this inquiry. To these have been applied the various forms of phosphatic manures, nitrogenous manures, potash-manures, guanos, and superphosphates. That is wherein they differ; but they all agree in this, that the manure of each plot contains 40 lbs. phosphoric acid, 30 lbs. potash, and 10 lbs. nitrogen. Hence, whatever differences may be observed in the amount or character of the crop on the various plots must be due not to the amount of plant-food supplied to them, but solely to the special form in which it has been applied. Care has been also taken to regulate, as far as possible, the amounts of the other important constituents of plant-food—viz., lime, magnesia, and sulphuric acid. The remaining five plots have been used for making separate experiments with other crops." The result of these valuable experiments will be watched with interest.

#### SCOTCH PRISONS.

THE seventeenth annual report of the managers appointed under the Prisons (Scotland) Act, 1860, has just been issued. In the Criminal Lunatic Department of the General Prison at Perth, 57 prisoners were in custody at the beginning of the year—41 males and 16 females; 4 were admitted and 6 disposed of during the year, leaving 55—39 males and 16 females—at the close; while the daily average was 56. Want of proper accommodation in the Lunatic Department is still complained of. Sense is expressed of the loss sustained by the department during the year through the retirement of Sir R. Christison from the position of visiting physician to the General Prison; and it is stated that Professor Douglas MacLagan has acted as temporary visiting physician in his room. It is recorded that a new hospital for male prisoners has been completed and brought into occupation during the year. Two cases of suicide are reported as having occurred in prisons during the year; in neither instance did blame attach to a prison-officer.

#### BATHGATE WATER-SUPPLY.

FOR some years past, the inhabitants of Bathgate have suffered much in the dry season from want of water; and since the opening of many public works in the district, the want has become very urgent. About twelve months ago, it was determined to construct a large reservoir about half a mile from the town, and at a height of seven hundred and ten feet above sea-level. The work was one of great difficulty, but it has been at length successfully accomplished. The reservoir will be supplied from the Well Burns and Petershill bore, along with about one hundred acres of watershed, and is capable of containing 12,000,000 gallons. It is calculated that this, in addition to the present supply, which is obtained from springs and bores about the burgh, will satisfy the requirements of the population for a long time to come. Several filters have been placed at a point nearer the town. The cost of the operations will not exceed the original estimate of £6,000. The ceremony of turning on the new supply was performed on June 7th by the wife of Mr. MacLagan, M.P.

### IRELAND.

FOUR deaths from small-pox were recorded last week in Belfast, being the highest number registered during the previous six weeks.

THE Mountmellick Board of Guardians have voted a retiring allowance of £86 *per annum* to Dr. Wilkinson of that Union, being two-thirds of his late salary.

At a meeting of the Ballinasloe Board of Guardians, last week, the medical officer reported an outbreak of small-pox in the Workhouse, introduced by a tramp from the King's county.

DR. MCCLINTOCK, ex-Master of the Rotunda Lying-in Hospital, and Mr. Chaplin, Surgeon to the County Kildare Infirmary, have intimated their intention of seeking election to the Vice-Presidency of the Royal College of Surgeons in Ireland next June.

#### QUEEN'S UNIVERSITY IN IRELAND.

THE examinations in the Faculty of Medicine of the University commenced in Dublin last Monday week, and concluded yesterday (Friday). Nearly seventy candidates presented themselves in the subjects for the first and second University examinations in medicine. A meeting of the University to confer degrees will be held on Monday next.

#### MEDICAL WITNESSES.

A CIRCULAR from Dublin Castle has been recently forwarded to the magistrates throughout Ireland, which states that the attention of the Government has been called to the great and unnecessary expense of medical witnesses at Assizes and Quarter Sessions, and impressing upon them the necessity of exercising great caution in the matter of summoning and binding witnesses to appear unless in important cases, or where it can be satisfactorily shown that such evidence is indispensable for rightly disposing of the case.

#### IRISH MEDICAL ASSOCIATION.

THE first meeting of the Council, since its election at the recent annual general meeting of this Association, was held in the Royal College of Surgeons in Ireland, on Tuesday last. The President, Dr. Robert McDonnell, occupied the chair. The following members were elected on the Committee of Council for the ensuing year: Dr. Thomas Purcell (*Chairman*), Dr. Minchin (*Honorary Treasurer*), Dr. J. W. Moore (*Honorary Secretary to Council*), Dr. Chapman (*Honorary Secretary*), Dr. Grimshaw, Dr. A. H. Jacob, Dr. Mayne, Dr. Pollock, and Dr. Speedy. Dr. Chaplin of Kildare was appointed a member of Council. In consequence of the increasing clerical work devolving upon the Honorary Secretary, it was resolved that a salaried assistant-secretary be appointed.

#### THE CASE OF DR. MEEHAN.

ON the 5th instant, the Guardians of Limerick Union received a letter from the Local Government Board, in reference to the recent removal of Dr. Meehan from the office of visiting medical officer to the Workhouse by sealed order. The Board stated that the Chief Secretary of the Lord-Lieutenant was in communication with Mr. Butt, M.P. for Limerick, on the subject; and that he is desirous that nothing further should be done in the case, until he has had a full opportunity of making to him any further statement which he may have in view, although at present the Chief Secretary has no reason to question the correctness of the decision arrived at in Dr. Meehan's case. After considerable discussion, the guardians decided, by a large majority, to postpone the election of a resident medical officer and a resident apothecary, pending the inquiry which is being held.

#### PRESENTATION TO DR. KINKEAD.

AN address and testimonial has been presented to this gentleman, on the occasion of his leaving Tuam, where he practised for the past ten years, consequent upon being appointed to one of the professorial chairs in Queen's College, Galway. The address stated, that his friends and well-wishers could not permit those social ties which bound him and them together to be severed without expressing their appreciation of his valued services, and offering their hearty congratulations on his well-merited promotion. Whilst they rejoice that he has been chosen to fill one of the chairs in the Queen's University in Ireland—a post which his high literary and scientific attainments eminently qualify him to occupy, and which will be congenial to his tastes and pursuits—the consciousness of losing, not only so genial and sincere a friend, but also so skilled and gifted a physician, causes heartfelt regret to mingle with their pleasure.

## THE DENTAL PRACTITIONERS' BILL.

THE following remarks were made by Mr. Tomes, F.R.S., and Mr. Donald Napier in the discussion of the Dental Surgeons' Bill at the recent meeting of the Parliamentary Bills Committee (see JOURNAL of June 8th, page 386).

Mr. TOMES drew the attention of the meeting to the fact that dental surgeon and surgeon-dentist were terms in constant use from the early part of the last century, during which period the latter term had been used by dental practitioners without interruption. In the case of Ladd v. Gould, it was decided by the Court of Queen's Bench that the Medical Act of 1858 had no authority over the above usage. It was decided that the term surgeon-dentist does not mean surgeon and dentist, and a rehearing of the case was refused. The licentiate in dental surgery of the College of Surgeons uses the title of dental surgeon by the same right that a Member or Fellow of the College uses that of surgeon; namely, that the one is, by a board of examiners in dental surgery organised in conformity with a Royal Charter, pronounced competent to practise dental surgery, and the other surgery. The title given to the former is Licentiate in Dental Surgery; to the latter, Member or Fellow of the College of Surgeons. The Dental Practitioners' Bill proposes that, for the future, all dental practitioners shall become licentiates; and that they shall as such be registered; but it does not legislate for the past. Persons at present in practice will, unless they hold a recognised qualification, be entered upon the *Register* as in practice before the passing of the Act, and they amount to about four-fifths of the whole number of dentists. As they die off, their places will be occupied by qualified practitioners. There are at present in the *Medical Register*, under the letter B, nine persons who are entered as in practice before 1815; that is, they have no recognised medical qualification. The powers given by the Dental Charter were permissive only, and the success which has attended its administration has led the way to compulsory legislation. But it would not be consistent with justice to deprive persons of privileges exercised through several generations without infraction of the law, by the creation of a new law; and the Licentiates in Dental Surgery would not consent that the meaning of the term dental surgeon should be changed, in order that they may be deprived of its use. All the surgical corporations of the United Kingdom have approved of the Bill, and the principles of the Bill have been approved by the General Medical Council. Sixty-eight dental practitioners who hold registered medical qualifications have petitioned in favour of the Bill, and we do not know of more than ninety persons so qualified. Taking dentists generally, upwards of twelve hundred, or two thirds, have petitioned Parliament in favour of Sir John Lubbock's Bill, the total number of dental practitioners being estimated at a little below two thousand.

Mr. W. DONALD NAPIER said that he dissented entirely from the views expressed by Mr. Tomes; but he wished it, at the same time, to be understood that he did so in no unfriendly spirit. The question before the Committee was one that affected the rights of the medical profession as a body, not those of one class of specialists only. It must be remembered that the framers of the Dental Practitioners' Bill had resolved upon the prohibition of duly qualified medical practitioners from practising dental surgery by right of the diploma that empowered them to treat, medically or surgically, every part of the human body; and, although this absurd clause had been eliminated from the amended form, the fact that it had been inserted remained to prove the aim and intention of those who drew up and promoted the Bill: to wit, the monopoly of a speciality. Failing that, they would fain secure to those who own merely a licence from the College of Surgeons permitting them to practise dental surgery, and to go far here—to those possessed of no qualification whatever, beyond that which they owe to a large brain plate in the nature of their calling, the right to style themselves "surgeon-dentist" or "dental surgeons," as their taste may suggest. It seemed to him (Mr. Napier) that the time had arrived for the medical profession to enter a strong protest against the assumption of any title calculated to mislead the public. The Medical Act of 1858, though preventing unqualified persons from assuming the title of physician or surgeon alone, failed to deter them from appropriating it in conjunction with another word, as, for example, surgeon-accoucheur, surgeon-auditor, surgeon-dentist, surgeon-oculist, and the like. It was, therefore, of grave importance that this loophole should be closed; and the presentation of the Dental Practitioners' Bill, and the Medical Act Amendments Bill, afforded opportunities that should not be lost of remedying an existing abuse. With regard to Mr. Tomes's assertion, that candidates for the membership of the College of Surgeons are not examined in the anatomy of the jaw, he could only say that his inform-

ation, derived from several of the examiners, was not in agreement with it; and, in reply to another remark from the same gentleman, to the effect that, whereas a mechanic might become a good dentist, an ordinary medical practitioner never could, or was unlikely to do so, he begged to express an entirely different opinion, believing that the educated medical practitioner could perfect himself in this, as in any other speciality of surgery, by devoting himself for a time to its study, and that the result would prove him to be the better dentist of the two. Mr. Napier concluded by expressing his regret that the subject of dental surgery did not meet with more attention than at present from the young men who joined the College as members, as, either in the army or navy, or in civil practice, the time might come when greater proficiency in this special branch might be found by them to be both useful and remunerative.

## THE HARVEY TERCENTENARY MEMORIAL FUND.

THE meeting of London subscribers which was to have been held on Wednesday last did not, in consequence of a resolution passed by the London Executive Committee, take place. Instead of it, there is to be a meeting of all the subscribers at the Royal College of Physicians, Pall Mall East, on Tuesday next, the 18th instant, at 5 P.M. The business of the meeting will be the following. 1. To receive a report from the London Executive Committee; 2. To receive a report from the auditors; and 3. To consider other important matters in connection with the objects of the subscribers. Further subscriptions are still required, and will be thankfully received by Sir George Burrows, Bart., or Mr. Prescott Hewett, the honorary treasurers; by Mr. George Eastes, M.B., 69, Connaught Street, Hyde Park Square, London, W.; or Mr. W. G. S. Harrison, B.A., Town Clerk, Folkestone, the honorary secretaries; or they may be paid in to the account of the Fund at the Western Branch of the Bank of England, Burlington Gardens, London, W.

## HOSPITAL AND DISPENSARY MANAGEMENT.

## THE PLYMOUTH PUBLIC DISPENSARY.

WE have on former occasions referred to the proposal which has been made to introduce the provident system into the Plymouth Public Dispensary. That there should be difficulties in carrying out such a proposal is only what was to be expected. We are glad, however, to learn that these difficulties have been overcome, and that a provident department has been engrafted on the Free Dispensary. At the same time, the Committee of Investigation—which was created by the original rules of the institution, but had fallen into abeyance—has been revived, and will watch over the interests of both the free and the provident departments. On the one hand, it will prevent, as far as possible, letters of recommendation from being used for improper persons; while, on the other hand, it will endeavour to promote the provident system. It is obvious, therefore, that everything will depend upon the activity of the Committee of Investigation. If it be strict and vigilant, the reforms now introduced into the Plymouth Dispensary will not only prove a great advantage to the town, but may also serve as a model to many other places.

## THE LEAMINGTON PROVIDENT DISPENSARY.

THE ninth annual report of the Leamington Provident Dispensary, which we have lately received, congratulates "the supporters of the institution upon its increasing popularity and usefulness amongst that class of the community for whose benefit it was established. The number of provident members has considerably increased, and the work has been carried on in every respect satisfactorily during the year." There is a decrease of £14 in the benevolent contributions, while the provident payments have increased by £46. If this indicate that there is any falling off of interest on the part of the public in this institution, we sincerely regret it; but, on the other hand, the more provident dispensaries become self-supporting, the better will they fulfil their object. There are now about four thousand enrolled members in this dispensary; and last year £387 13s. 9d. was divided among the four medical officers.

## THE CITY PROVIDENT DISPENSARY.

WE are glad to learn that a provident dispensary has been established in the heart of the city. It would be well if some of the older dispensaries in this quarter would reform themselves upon this model. The basis upon which this new institution stands has been so often

recommended by us, that we need not say we approve of it. It is, however, distinguished from others in having a "Surgical Appliance Branch" attached to it, from which the patients can obtain trusses, elastic stockings, etc., on favourable terms and by easy instalments; but we are sorry to observe, that for the more expensive instruments, the system of requiring "Governors' cards" has been adopted. We trust these "Governors' cards" are dispensed by the Committee, and that poor cripples have not to go round the town begging for them. The surgeons, who undertake to attend and see patients every day from 10 to 11 A.M., from 1 to 2 P.M., and again from 6 to 7 P.M., are perhaps a little liberal of their services. To require medical men to give evening attendance at public institutions is to lay a heavy burden upon the profession.

## CORRESPONDENCE.

### VOTING FOR COUNCILLORS.

SIR,—I perceive you are publishing various letters on the question as to who are the proper persons to be elected members of the Council of the Royal College of Surgeons of England. It appears to me that one very important fact, in connection with that election, has been overlooked by the various writers on the subject, viz.: that, practically, the greater number of Fellows are disfranchised by the fact that it is necessary to be personally present at the election in order to vote. I should like to ask the intending candidates for the honour of the position of members of the Council of the College, whether they would be prepared to vote in favour of an alteration of that law: to allow, as is the case in many other elections, voting by voting-papers, sent round to the Fellows beforehand. If it would be in order, I should be happy to attend at the meeting for the election, in order to support any influential Fellow who would move a resolution to recommend an alteration of the by-laws, to that effect, to the Council.

I remain yours obediently,

GEORGE JACKSON, F.R.C.S. Eng. (Exam.)

Plymouth, June 10th, 1878.

### THE METROPOLITAN COUNTIES BRANCH AND ASSOCIATION VOTING.

SIR,—A careful perusal of the laws of the Association and of its Metropolitan Counties Branch will, I think, convince your readers that there is absolutely no reason why the administrative action of the Executive should ever be seriously embarrassed by any supposed conflict of written papers with the vote of members in meeting assembled, which latter alone, as you point out, has official weight; the former, however valuable as a means of obtaining an expression of opinion from individual members of the profession, not being the mode in which, as members of the Association, they have agreed to record their votes, and the Executive, whatever their personal feelings or sympathies may be, being bound to carry out the legally expressed wishes of the members.

In the case of the late meeting of the Metropolitan Counties Branch, moreover, I contend that there has not been any contradiction (much less an official contradiction) between the so-called written votes of metropolitan members and the regularly obtained vote of the Branch.

This will at once be evident if we put together in the form of question and answer the queries to which the individual members replied, and a part of the resolutions passed by the Branch. Thus: Q. Are you of opinion that the medical profession should be directly represented in the General Medical Council?—A. It is desirable that the voice of the profession should be expressed in the Council by means of direct representation (4th Resolution).—Q. Are you of opinion that the establishment of a conjoint board for the granting of licences to practise all branches of the profession should be made compulsory in each of the three divisions of the kingdom?—A. It is desirable that the formation of conjoint examining boards should be made compulsory in each division of the kingdom (2nd Resolution).

Had it been desired to obtain an expression of opinion on the point really at issue between those who support and us who oppose the action of the Medical Reform Committee, a third query ought, I think, to have been added, something like this: Are you of opinion that we should repeat the policy pursued by us in 1870, and, like the Irish obstructives, oppose all medical legislation that does not provide for direct representation? and, put in that form, I have little doubt that the answer given in the written papers would have been substantially the same as that given by vote of the Branch—No, certainly not!

However this may be, it is, I think, very desirable that the amended

Bill should be brought under the consideration of the Branch at the earliest possible moment. My friend Mr. R. H. S. Carpenter, to whom the profession is more indebted than to any other man in England for the enforcement of the law against quacks, tells me that the amended Bill will leave the profession in a worse position as regards these gentlemen, and also as regards practising chemists, than it is already, since it proposes to repeal the sections of the Apothecaries' Act, under which most of the successful prosecutions have been carried on, and to give nothing satisfactory in its place. The change also which has been made in the Bill while passing through Committee in the House of Lords, by which those who pass the conjoint boards will be able to register without connecting themselves with any of the corporations, is open to the objection urged by Dr. Quain with reference to colonial and foreign practitioners, that there would then be no check upon their professional conduct.

The title, too, which is to be conferred by this qualifying certificate system is open to discussion. One of your contemporaries has well pointed out that "medical practitioner" when shortened to M.P. would create confusion, and that Q.C. would also be liable to be misunderstood.

The Bill has passed rapidly through the Upper House; and, unless action be taken by our Branch at once, these and other important points may not receive sufficient attention in the House of Commons.—Faithfully yours,

H. NELSON HARDY.

### IS ALCOHOL FOOD?

SIR,—A family bereavement has prevented an earlier reply to the letter of Dr. Markham, and is my apology to the members of the Association for not having taken an earlier notice of that communication.

Dr. Markham calls in question the truth of a certain statement which I made in my address on Alcoholic Drinks, viz., that every medical man (in extensive practice) must have seen cases which now and then have fallen to my lot to witness, in which life had been prolonged by the stimulants which the patients would alone consume. Dr. Markham omitted one very important and qualifying part of the statement. I said "every medical man in extensive practice"; I should also have said in extensive family practice. If Dr. Markham is excessively interested in this fact, I will show him a case which is now under my care, and which I have carefully watched for some years. The patient existed for some months entirely on stimulants, and during more than three months she did not take two ounces of any other kind of food. There was no deception in the case. The parents and sisters who attended upon her, and who tried all kinds of methods of getting other food taken, entirely failed to do so. It is true she became, and still is, a skeleton; but the fact remains that absolutely no other food was taken for a length of time than that which I have mentioned.

When I delivered the oration, I had also two other cases in my mind in which two old ladies lived on stimulants alone for several weeks before death, and I have no reason to suppose that I was deceived by the attendants. Almost every large private lunatic asylum will probably contain cases which are of a similar character.

I might have declined to answer Dr. Markham; I do not think he is quite aware of the offensive style in which he has put his question. I will, however, pass that by, and simply remark that, on asking for the grounds on which an argument is founded, it is not necessary to charge your antagonist with falsehood.—I am, sir, your obedient servant,

Croydon, June 10th, 1878.

ALFRED CARPENTER.

## ASSOCIATION INTELLIGENCE.

### COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 10th day of July next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

General Secretary.

36, Great Queen Street, London, W.C., June 12th, 1878.

### EDINBURGH BRANCH.

THE annual general meeting of the above Branch will be held at 5, St. Andrew's Square, Edinburgh, on Tuesday, June 18th, at 4 P.M.: Sir ROBERT CHRISTISON, Bart., President, in the Chair.

CHARLES E. UNDERHILL, *Honorary Secretary.*

Edinburgh, June 4th, 1878.

### CAMBRIDGE AND HUNTINGDON, EAST ANGLIAN, AND SOUTH MIDLAND BRANCHES.

A CONJOINT meeting of these Branches will be held at Peterborough, on Friday, June 21st; T. J. WALKER, M.D., President-elect.

#### PROGRAMME OF PROCEEDINGS.

11.45 A.M. Each Branch will meet separately at the Peterborough Infirmary, to transact Branch business.

12.30 P.M. Morning general meeting: President's address, etc.

1.15 P.M. Luncheon at residence of President-elect.

2.15 P.M. General meeting for the reading and discussion of papers, etc.

5.0 P.M. H. M. Townsend, Esq., architect, will conduct a party over the Cathedral and surrounding buildings.

6.0. Dinner at Great Northern Hotel. Tickets 15s. each, wine inclusive.

The President-elect will be obliged if those members who propose to attend the dinner will communicate their intention to him not later than Monday, the 17th instant.

The following papers have been promised.

1. J. B. Bradbury, M.D., Cambridge: Notes of two Cases of Obscure Disease of the Liver: with Remarks.

2. F. Buszard, M.D., Northampton: A Case of Pseudo-hypertrophic Paralysis.

3. W. Cadge, Esq., Norwich: The Diagnosis and Complications of Diabetes.

4. Peter Eade, M.D., Norwich: Case of Chronic Dysentery treated by Milk only.

5. A. Haviland, Esq., Northampton: The Distribution of Zymotic Diseases from Epidemic Centres.

6. G. M. Humphry, M.D., F.R.S., Cambridge: 1. Hospital Practice in Norway, Sweden, and Russia; 2. Case of Recovery after Removal of a Fungous Growth in the Bladder.

7. John Lowe, M.D., Lynn: Lithotomy in a Case of large Phosphatic Calculus, the Nucleus being a Bone Penholder, which had been two years in the Bladder.

8. W. Newman, M.D., Stamford: The 'Antiseptic Dressing of Wounds.

9. C. E. Prior, M.D., Bedford: Five years' Experience of Enteric Fever by a Medical Officer of Health.

10. W. Thomson, M.D., Peterborough: Notes on Gastrotomy in a Case of Stricture of the Esophagus: with Report of a Successful Case.

11. Job Watson, Esq., St. Ives: A Case of Severe Gunshot Wound of the Skull terminating in Complete Recovery.

12. George Wherry, B.A., Cambridge: On the Disadvantages and Disorders of Hypermetropic Eyes.

Dr. T. S. Walker will be glad to arrange for the reception for the night, by himself or his friends, of members from a distance, for whose return there is no late evening train.

All qualified members of the profession residing in the neighbourhood are invited to attend the meeting, even if not members of the Association.

WM. A. ELLISTON, M.D., Ipswich,

J. B. PHIL, M.D., Norwich,

BUSHELL ANNINGSON, M.D., Cambridge, } *Honorary Secretaries.*

G. F. KIRBY SMITH, Northampton,

### LANCASHIRE AND CHESHIRE BRANCH.

THE forty-second annual meeting of this Branch will take place at Bailey's Hotel, Blackpool, on Friday, June 28th, 1878, at 1 P.M.; Dr. STEELE (Liverpool) President.

The following communications have been promised.

1. Mr. Reginald Harrison: On the Use of Filiform Bougies with Tunnelled Instruments (Gouley's) in the Treatment of Stricture of the Urethra.

2. Dr. Haddon: 1. Two Cases of Ulcerating Endocarditis, with Temperature Charts and Sphygmographic Tracings; 2. An Easy Way of Noting Cases in General Practice.

3. Dr. Howie: The Grape-Cure in Bilious Nausea and Early Pregnancy.

4. The Report of the Duration of Infection Committee will be read, and a summary of the results obtained will be given.

The members will dine together at Bailey's Hotel, at five o'clock. Charge 7s. 6d., exclusive of wine. Gentlemen intending to be present at the dinner are requested to forward their names to Dr. Leslie Jones, Blackpool, not later than June 24th.

D. J. LEECH, M.D., *Honorary Secretary.*

Manchester, June 13th, 1878.

### BATH AND BRISTOL BRANCH.

THE annual meeting of the Branch will be held at the Mineral Water Hospital, Bath, on Wednesday, June 26th, at 4.30 P.M., when H. MARSHALL, M.D., will resign the Chair to H. HENSLEY, M.D. The members will afterwards dine together at the York House.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, June 4th, 1878.

### MIDLAND BRANCH.

THE annual meeting of this Branch will be held at Lincoln, on Thursday, June 27th: President—C. H. MARRIOTT, M.D.; President-elect, A. MERCER ADAM, M.D.

Members desirous of reading papers are requested to communicate with C. HARRISON, M.D., *Honorary Secretary.*

Lincoln, May 14th, 1878.

### SOUTH-WESTERN BRANCH.

THE annual meeting of this Branch will be held at the Imperial Hotel, Torquay, on Thursday, June 20th, at 1.50 P.M.

Luncheon (provided by Dr. Radclyffe Hall, President-elect) will be from 11.30 A.M. to 1 P.M.; and dinner (7s. 6d., exclusive of wine) at 5.15 P.M.: both at the Imperial Hotel.

Gentlemen wishing to read papers, or to dine, are requested to give notice to the Secretary on or before the 18th instant.

LOUIS H. TOSSWILL, M.B., *Honorary Secretary.*

Exeter, June 12th, 1878.

### NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held at Hartlepool, on Thursday, July 25th, at 3 P.M.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, June 8th, 1878.

### BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, July 2nd. The Chair will be taken by the President, SAMPSON GAMGEE, Esq., at 3 P.M.

An address will be delivered by the President-elect, Dr. TIBBITS, of Warwick.

The annual dinner will also take place at the Midland Hotel, at 5 P.M. precisely, for the convenience of country members. Dinner tickets, exclusive of wine, 7s. 6d. each.

JAMES SAWYER, M.D., } *Hon. Secretaries.*  
EDWARD MALINS, M.D., }

Birmingham, June 11th, 1878.

### SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE annual meeting of this Branch will be held at Neath, on Thursday, July 11th: J. TALFOURD JONES, M.B., President; JOHN RUSSELL, Esq. (Neath), President-elect.

Any members desirous of reading papers, etc., are requested to communicate the titles to either of the Honorary Secretaries.

ANDREW DAVIES, M.D., } *Honorary Secretaries.*  
ALFRED SHEEN, M.D., }

June 12th, 1878.

### SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

A MEETING of this district was held at the Star Hotel, Lewes, on Friday, May 24th; N. P. BLAKER, Esq., of Brighton, in the chair. Sixteen members and visitors were present.

*Communications.*—The following communications were made.

1. Mr. PENFOLD of Brighton showed a Photograph of a Tumour in the Left Orbit occurring in a married woman, and related its history and treatment.

2. Mr. BLAKER read particulars of three cases of Visceral Syphilis; viz., a. Large Gummata of Liver, one situated in the Lobus Spigelii causing Obstruction of the Portal Veins and Dropsy; b. Syphilitic Deposit in Liver and Head of Pancreas obstructing the Ductus Communis Choledochus; c. Syphilitic Disease of the Dura Mater producing Epileptic Fits, the second fit being fatal.

3. Dr. W. WITHERS MOORE related a case of Hemiplegia and Subsequent Apoplexy from Embolism.

*Deaths of Members.*—Mr. BLAKER moved, Mr. GRAVELY seconded, and it was carried: "That this meeting cannot separate without expressing their deep regret at the lamented death of the late Dr. Cunningham of Hailsham, one of the Vice-Presidents of this Branch; and also of Mr. Whitefield of Eastbourne."

*The Dinner* took place at the Star; Mr. Blaker in the chair.

*The Next Meeting* is to be held at Hayward's Heath in September; and Dr. Braid was nominated to fill the chair.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### THE HOLLINGBOURN BOARD OF GUARDIANS AND OUTDOOR MEDICAL RELIEF.

THE guardians of this rural union some time since appointed a Committee to consider the question of outdoor relief. Their report, signed by the chairman, J. Paine, is before us; from that and other official sources we will proceed to lay before our readers certain facts well worthy of consideration.

The Hollingbourn Union, Kent, comprising an area of 60,555 acres, contains a population of 14,047. This area and population are distributed into six medical relief districts, which vary remarkably in extent and population. In the year 1876-77, the cost of gross relief was £7,115, being at the rate of 10s. 1½d. per head of population; medical relief amounting to only £345 10s., inclusive of extras, which were £29 10s. From the return furnished at the instance of Dr. Lush, we learn that this board has paid no heed to the recommendation of the Select Committee on Poor Relief, 1864, which reported in favour of boards of guardians providing all expensive medicines; for this board supplies none—not even cod-liver oil for the consumptive and scrofulous sick. The importance of efficient medical relief in diminishing the duration, and therefore the costliness, of sickness when occurring among the wage-earning classes, has evidently never dawned on their minds, or we should not find in the rules and regulations which this board has drawn up the following. Able-bodied men eligible for relief, belonging to any club and falling sick, first, in all cases, to have medical relief on application; secondly, in all cases where the club-pay exceeds fourteen shillings a week, no relief to be given beyond the medical order; which, being interpreted, means that the guardians will not sanction the grant of any relief which is to cost the board anything, but that they will not object to saddling their ill-paid medical officers with the charges for visiting and the provision of medicines and appliances. The heavy poor-relief outlay, the smallness of pay and general insufficiency of the medical relief arrangements, prove conclusively that it is to the starvation of the latter that the excessive amount of the former is due. What inducement can there be for frequent visits or liberality in prescribing, on the part of medical officers serving such a parsimonious board? These rules and regulations for limiting outdoor relief are conceived in a very illiberal spirit, and show that such boards as this of Hollingbourn have erroneous notions of the manner in which they should deal with the arrangements which relate to the medical care of the poor committed to their charge. We are satisfied that they will fail in securing the end the board is striving to obtain; viz., the diminution of the charges on poor-relief.

## MILITARY AND NAVAL MEDICAL SERVICES.

### NETLEY TRAINING.

THE *Army and Navy Gazette* publishes the following paragraph.

"In referring three weeks since to the call upon the medical profession to provide candidates for immediate entry as naval surgeons, we pointed out the objection felt by many qualified practitioners to pass the required examination and to go through the course at Netley. Our remarks have called forth the approval of one of very high standing in the profession, who, from his position, should be able to gauge the feeling of would-be candidates, and he remarks that 'for the Netley staff to presume to test the qualifications of men whose names are on the official register is a piece of presumption without a parallel, and the great stumbling-block to obtaining a sufficient supply of medical candidates for the public service'. We trust their lordships will not let this opinion pass unnoticed."

We can assure our contemporary that, however high be the standing of the gentleman in question, the information with which he has furnished

does not accord with the general feeling in the civil profession, in the service, or in the medical schools, but can represent the crotchets only of very few. We believe, indeed, that such a statement is not only unfounded, but the exact and complete reverse of the fact. The immense advantages of a course of Netley training to the army medical officer has long been recognised; and the boon lately secured to the navy of participating in the advantages of that course is very generally and largely appreciated. No doubt, the incapable, the indolent, and the frivolous, who see in the medical services of the army and navy only a chance of idling or masquerading on a secured pittance, or of securing a living which imperfect attainments and constitutional indolence make doubtful in the competition of home life—such men shrink from the further labour of the Netley course and the tests of increasing and special proficiency which it provides. But the army and the navy have great cause to remember with gratitude those who founded and those who carry on that admirable school of special technical training for the services. A proof, moreover, that the fear of Netley is not the cause of the dearth of candidates is afforded in this particular instance, when the special announcement that the Netley course would be omitted, the implied indication that examination-tests would be specially lenient, and the spirit-stirring prospect of early active service, failed to secure even the limited number of candidates required. The fact is, that the conditions of service require to be further improved in the direction already long since laid before the Admiralty by impartial and well-informed persons, of which a summary was formally presented to the First Lord by the Parliamentary Bills Committee of the British Medical Association.

## OBITUARY.

### ROBERT GARDINER HILL, L.R.C.P.E., F.S.A.

ROBERT GARDINER HILL died suddenly, of apoplexy, at his residence, Earl's Court House, Old Brompton, on May 30th. He was born in Louth in 1811, was educated at Guy's and St. Thomas's Hospitals, and qualified as M.R.C.S. and L.S.A. in 1834. He became L.R.C.P.Ed. in 1859. In 1834, he was appointed house-surgeon to the General Dispensary at Lincoln; in the following year, he was elected medical superintendent to the Lincoln Lunatic Hospital, which office he held for five years. He afterwards practised at Lincoln, and became proprietor of Eastgate House, a private asylum for the insane. He was very popular in Lincoln, and was chosen mayor of the town in 1852. He subsequently removed to London, and became proprietor of Earl's Court House, a private lunatic asylum, and once the house of John Hunter. Of Mr. Hill's services in the improved treatment of the insane, we speak in another column.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having undergone the necessary examinations for the Fellowship at the half-yearly meetings terminating on the 3rd instant, were reported to have acquitted themselves to the satisfaction of the Court of Examiners; and, at a meeting of the Council on the 13th instant, were admitted Fellows of the College.

Messrs. Charles Firth, Norwich, diploma of membership dated November 18th, 1873; Charles E. Harrison, Army, January 21st, 1874; Harold B. Boulter, Hull, July 27th, 1874; George H. Hames, Leicester, April 20th, 1875; Frederick S. Edwards, St. Peter's Park, W., November 17th, 1875; and Robert H. A. Schofield, Cambridge Gardens, May 23rd, 1877 (Students of St. Bartholomew's Hospital); Edward F. Brockman, Addison Gardens, November 14th, 1865; and William A. Frost, Ladbroke Square, July 22nd, 1874 (of St. George's Hospital); George E. Williamson, North Shields, April 21st, 1874 (of the London Hospital); Francis R. Cross, Bristol, January 25th, 1871 (of King's College); Rhinallt N. ap J. Pughe, Liverpool, April 22nd, 1873 (of the Liverpool School); Frank T. Paul, Liverpool, July 22nd, 1873; George A. Wright, Romford, April 25th, 1877 (of Guy's Hospital); Bernard M. S. Roth, Wimpole Street, July 23rd, 1874 (of University College); Horace Manders, Marlborough, November 16th, 1875 (of St. Mary's Hospital); and Gerald F. Yeo, Albemarle Street, not a member (of the Dublin, Paris, Berlin, and Vienna Schools).

Five candidates, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for twelve months.

At the same meeting of the Council, the following members were elected Fellows of the College.

Messrs. J. Hyde Houghton, Dudley, diploma of membership dated April 2nd, 1858; R. James Mann, Wandsworth, June 26th, 1840; and W. Berry Kellock, Stamford Hill, May 5th, 1843.

**APOTHECARIES' HALL.**—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 6th, 1878.

Hine, Alfred Leonard, Oakley Street, Chelsea  
Prince, Herbert Francis, Park Street, Taunton  
Stewart, John McDougall, 12, Cambridge Gardens, N.W.  
Taylor, Richard Stanley, Friar Gate, Derby

The following gentleman also on the same day passed his primary professional examination.

Livy, Frederic Young, Manchester Hospital

### MEDICAL VACANCIES.

THE following vacancies are announced:—

**BIRMINGHAM GENERAL HOSPITAL.**—Assistant Physician. Salary, £100 per annum. Applications to be made on or before the 24th instant.

**BRIGHTON HOSPITAL FOR SICK CHILDREN.**—House Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing.

**EAST RIDING LUNATIC ASYLUM.**—Medical Superintendent. Salary, £350 per annum, with furnished house, coals, and gas. Applications to be made on or before the 24th instant.

**GREAT NORTHERN HOSPITAL.**—Surgeon to the Out Patients' Department. Applications to be made on or before July 2nd.

**HOSPITAL FOR SICK CHILDREN, MANCHESTER.**—Junior Resident Medical Officer. Salary, £50 per annum, with board and residence. Applications to be made on or before the 25th instant.

**KENMARE UNION.**—Medical Officer to Kenmare Dispensary District. Salary, £100 a year, with £25 as Sanitary Officer, and the usual Registration and Vaccination Fees. Applications on or before the 25th instant.

**KENT AND CANTERBURY HOSPITAL.**—Physician. Applications to be made on or before the 24th instant.

**LIMERICK UNION.**—Apothecary to Workhouse. Salary, £100 a year, with apartments, fuel, and light; but applications will be received for the post at £100 a year, with permission to reside in Limerick. Election will take place on the 14th inst.

**LONDON LIVER HOSPITAL.**—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance.

**MANCHESTER ROYAL INFIRMARY, DISPENSARY, and LUNATIC HOSPITAL.**—Ophthalmic Surgeon. Applications to be made on or before the 27th instant.

**MIDDLESEX HOSPITAL.**—Assistant-Physician. Applications to be made on or before July 2nd.

**RAMSGATE and ST. LAWRENCE ROYAL DISPENSARY and SEAMEN'S INFIRMARY.**—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, gas, firing, and attendance. Applications to be made on or before July 1st.

**ROYAL HOSPITAL OF BETHLEHEM.**—Assistant Medical Officer. Salary, £300 per annum, with furnished apartments. Applications to be made on or before the 26th instant.

**ST. MARLBOROUGH GENERAL DISPENSARY.**—Honorary Physician. Applications to be made on or before July 1st.

**SEAMEN'S HOSPITAL, GREENWICH.**—House Physician. Salary, £75 per annum; and House-Surgeon, salary, £50 per annum, with board and lodging in each case. Applications to be made on or before the 27th instant.

**SOMERSET COUNTY LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £120 per annum, with board, residence, and washing.

**SOUTH DEVON AND EAST CORNWALL HOSPITAL.**—House-Surgeon. Salary, £50 per annum, with board. Applications to be made on or before July 24th.

**TOWNSHIP OF MANCHESTER.**—Assistant Medical Officer. Salary, £140 per annum, with furnished apartments, washing, attendance, etc. Applications to be made on or before the 14th instant.

**WESTBOURNE PROVIDENT DISPENSARY.**—Surgeon. Applications to be made on or before the 24th instant.

**WEST BROMWICH DISTRICT HOSPITAL.**—House Surgeon. Salary, £80 per annum, with board, residence, and washing. Applications to be made on or before the 27th instant.

**WOLVERHAMPTON and STAFFORDSHIRE GENERAL HOSPITAL.**—House-Physician. Salary, £100 per annum, with board, washing, and apartments. —House Surgeon. Salary, £100 per annum, with board, washing, and apartments. —Honorary Physician. Applications to be made on or before the 24th instant.

### MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

Dr TATHAM, H. M.D., appointed Obstetric Physician to the Jansjee Jejeebhoy Hospital, and Professor of Midwifery in the Grant Medical College, Bombay.  
GREENE, Richard, L.R.C.P.L.D. (Medical Superintendent of the East Riding Asylum, Beverley), appointed Medical Superintendent of the Northampton County Asylum, 27, G. Millon, L.R.C.P., resigned.  
\*MORRIS, A. Stanford, M.B., C.M., appointed Assistant Surgeon at the Royal South London Ophthalmic Hospital.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

#### MARRIAGES.

PIERCE—Pierce. On June 6th, at Platt Unitarian Chapel, Rusholme, by the Rev. C. Beard, B.A., uncle of the bride, Frederick Morrish Pierce, M.D., L.R.C.P. (London), of Manchester, to Hannah Sophia (Sophie), only daughter of John Pearson, J.D., of Heald Grove, Rusholme, late of Staleybridge.

### OPERATION DAYS AT THE HOSPITALS.

**MONDAY.**..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.**..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY.**..... St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY.**..... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY.**..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY.**..... St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

### MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**MONDAY.**—Royal College of Surgeons of England, 4 P.M. Mr. T. Spencer Wells, "Lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours". Lecture IV: Details of Different Steps in the Operation of Ovariectomy—Position of Patient—Incision—Adhesions—Opening and Emptying of Cyst—its Removal—Treatment of Pedicle—Closure of Wound—Dressing and After-Treatment.

**WEDNESDAY.**—Royal College of Surgeons of England, 4 P.M. Mr. T. Spencer Wells, "Lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours". Lecture V: Results of the Operation—History of Recovered Patients—Proportion of Incomplete Operations, and the Results—Cases of Recurrence and Second Operation—Successive Changes in the Mode of Operating and After-Treatment.

**FRIDAY.**—Royal College of Surgeons of England, 4 P.M. Mr. T. Spencer Wells, "Lectures on the Diagnosis and Surgical Treatment of Abdominal Tumours". Lecture VI: Antiseptics in Abdominal Surgery; Surgical Treatment of Uterine Tumours.

### LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

#### THE TITLE OF DOCTOR.

We have received again a very large number of letters on the subject of medical titles. Speaking generally, members in possession of an University M.D. of Scotland or Ireland are astonished at the puerility of those who claim the title of Doctor without possessing the University diploma. The opposite opinion prevails among correspondents who have been educated in England, where the facilities of a complete medical education are great, but opportunities for graduation as M.D. are denied to all but a very small minority of medical students. We cannot publish all these letters, or even a small proportion of them; and, indeed, although their number, and the frequency with which the correspondence is renewed, show that a very strong feeling prevails, we cannot say that they add anything to arguments already advanced. Persistence and number, however, constitute an argument in themselves; and, as we have already said, we can but recognise the fact, that, while the title of Doctor is denied to all but University graduates, completely educated English medical men labour under a plain disadvantage in comparison with graduates who, with no higher education, but with local advantages of title, settle alongside of them in practice.

ERRATUM.—A. H. T. C. was last week informed that the title of Mr. Birkett's work is *Diseases of the Heart, and their Treatment*; it should have been *Diseases of the Breast, and their Treatment*.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

#### SPELLING REFORM.

SIR,—The columns of the **BRITISH MEDICAL JOURNAL** are scarcely a suitable place for discussing the reform in the spelling of English, proposed by Dr. G. Harley, and exemplified in his paper published in the **JOURNAL** of June 8th. Nevertheless, as, if called on to adopt Dr. Harley's orthography, I should feel some strong pricks in my etymological conscience—and I do not think that they would be simply "needles"—I must beg leave to say a word or two on the subject.

In his ejection of the "needless" duplicated consonants, Dr. Harley seems to ignore certain well known phonetic tendencies of the English language. Again, the omission of the second consonant in many words is liable to give rise to ambiguity, which may partake more or less of the ridiculous. Would Dr. Harley, in describing a *post mortem* examination, write that the parts were "mated" together by adhesive lymph? Would he speak of the "anals" of physiology, or surgery, or any other science? And are we to "felo" his plan so far as to describe him and many other eminent and most respected men as "*Felo* of the Royal College of Physicians," "*Felo* of the Royal College of Surgeons," or "*Felo* of the Royal Society"?—I am, etc.,

SIR,—I was much interested and pleased with Dr. Harley's new method of spelling, for he has had the courage to put into practice ideas I have entertained for some time. Although Mr. Pitman's system is phonetically and philosophically correct, it makes no progress towards general adoption, because it is a *revolution* of the present system of spelling rather than a *reform*. Dr. Harley's method is a continuation of the alterations in spelling which have been slowly going on since the time of Chaucer, but arrested during the present century by the fixidity given to the English language by the adoption of standard lexicons. From these arbitrary standards writers and printers dare not depart, for fear of being charged with ignorance. Now, ours being considered one of the learned professions, its members need not fear the imputation of ignorance; therefore, if there could be a general agreement amongst us that we should in our correspondence and publications adopt Dr. Harley's method, the public would soon follow our example, and a spelling reform be accomplished. I would suggest that some influential members of our Association give notice that they will, at the next meeting, move that the **JOURNAL** in future be printed after the new method.—I am, etc., R. E.

P.S.—Dr. Harley's pamphlet should be advertised in the **JOURNAL**.

MR. P. MOSTYN WILLIAMS's letter reached the office on Thursday, and therefore too late for insertion this week: but it shall appear next week.

#### VACCINATION IN CHINA.

SIR,—As the benefits derived from vaccination, although fully established, seem still to be doubted by a few persons, through some isolated instances of unsuccess, it may perhaps not be out of place to state how rapidly vaccination is gaining ground among the "black-haired" race to whom small-pox has always been so great a scourge. In the spring, and occasionally the winter months, when the weather is milder than usual, small-pox makes sad havoc among the Chinese, to mitigate which, beside making burnt offerings to the Goddess of Small-pox, they for hundreds of years have resorted to a practice once adopted extensively by us, although differently from the Chinese—viz., inoculation. Small-pox is called by the Chinese "heaven's flowers", and inoculation "cultivating heaven's flowers". The latter appellation is likewise applied to vaccination. Inoculation is practised as follows. A lucky day is selected for the operation: this by the Chinese is held to be of great importance, as likewise choosing a lucky spot to deposit a coffin containing a dead body. They never bury their dead, nor have they cemeteries or burial-grounds. China may justly be said to be one vast mortuary, coffins being deposited anywhere and everywhere. Scabs are taken from a small-pox patient, pulverised, and blown up the nostrils of the child; the right nostril in the case of a female child, the left in that of a boy. Another method is to put the clothing of a patient with small-pox upon the child. A third method I have seen extensively practised, both at Ningpo and Wenchow, as follows. Children's nostrils are plugged with scabs and raw cotton, rammed in so tightly as to cause the ale to bulge out and blood to stream into the mouth. No particular rules are observed in selecting the matter, except that they always take it from a mild case of the disease. They take care at the time of inoculation that the child is in good health. They say they prefer inducing the disease at an early age, as by this means they prevent the child from scratching the pustules and causing pitting, and also that it is impossible to foretell whether the disease will be severe or not. Some years the mortality is much the same as from small-pox; in others, there are few if any deaths.

On the introduction of vaccination to China, it was considered by these intensely superstitious people to be some evil device of the foreigners. However, seeing the protection it gave to us, they were induced to try it, and for some years past it has been gradually gaining favour; but the Chinese will not submit to vaccination, unfortunately, during the winter months. So much benefit have the people of the far East derived from vaccination, that natives are rapidly taking up the practice; and according to the last Chinese Customs' Medical Report, Dr. Somerville of Foochow states that a curious document was posted on the walls in the neighbourhood, which, translated, is as follows.

"Vaccination was introduced hither from Europe. It is practised by 'planting' three 'seeds' of virus in a spot upon the left and right arms above the elbows. This spot is called the cold-dispelling pool, and upon it is formed the virus and a scab, there being no eruption upon the body generally. The result is effected in ten days, and no failure can possibly take place, whilst security is obtained from any natural and original attack of small-pox, or from a second attack, if the patient have already had it. Children vaccinated in this way need not be afraid of exposure to cold, thunder, chills, heat, etc.; nor need they take any medicine, whatever, or avoid any particular kinds of nourishment, but may play about just as usual. Persons wishing vaccination, should come to the house of the undersigned and make an appointment for the operation. Vaccination will commence on the 1st of November, 1877."

As Dr. Somerville writes, it is amusing to note the droll mixture of practical science from the West with the transcendentalism of the Chinese system of medicine. However, I think these few remarks will go far to prove the benefits that this nation must have derived from vaccination, which is so proverbially slow to adopt any Western ideas on any subject.—Truly yours, GEO. CHAS. COLES.

"**BRAIN**" asks whether any good memoir of the late eminent physician and metaphysician, Dr. John Abercrombie of Edinburgh, is in print.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### COMPOSITION AND QUALITY OF THE METROPOLITAN WATER IN MAY 1878.

The following are the returns made by Dr. C. Meymott Tidy to the Society of Medical Officers of Health.

Names of Water Companies.	Total Solid Matter per Gallon.	Oxygen used to Oxidise Organic Matter.	Nitrogen As Nitrates, &c.	Ammonia		Hardness. (Clarke's Scale.)	
				Saline.	Organic.	Before Boiling.	After Boiling.
<i>Thames Water Companies.</i>							
Grand Junction ..	10.40	0.066	0.120	0.000	0.000	13.2	2.8
West Middlesex ..	1.25	0.004	0.120	0.000	0.010	13.2	3.3
Southwark and Vauxhall .....	10.00	0.077	0.135	0.000	0.000	13.2	3.3
Chelsea .....	10.40	0.050	0.135	0.000	0.017	12.6	3.7
Lambeth .....	20.60	0.063	0.135	0.000	0.003	13.7	2.8
<i>Other Companies.</i>							
Kent .....	32.00	0.001	0.450	0.000	0.001	20.6	7.5
New River .....	17.00	0.024	0.144	0.000	0.000	12.6	3.7
East London ....	10.10	0.049	0.135	0.000	0.007	12.1	3.3

*Note.*—The amount of oxygen required to oxidise the organic matter, nitrates, etc., is determined by a standard solution of permanganate of potash acting for three hours; and in the case of the metropolitan waters, the quantity of organic matter is about eight times the amount of oxygen required by it. The water was found to be clear and nearly colourless in all cases.

#### MUSCÆ VOLITANTES.

SIR,—Allow me to remind your correspondents of the work of Donders, *On the Accommodation and Refraction of the Eye*, published by the New Sydenham Society. They will there find that this subject has received not only the attention of some of the highest authorities on optics, as Sir D. Brewster, but also the closest investigation of the best oculists of this age, as Listing, Liebreich, Doncan, and others. As the subject is fully gone into in the above admirable work, I will not presume to offer more than one or two remarks which have occurred to me. Muscæ appear at all times and in all shapes, in children as well as in adults; nor am I aware that any of the diseases named by Dr. Holland are at all necessary for their existence. They also appear at all distances, from the focal to three and two inches, immediately on the eye and within the orbit. Fixed muscæ are seen with the eyelids closed, because light is still transmitted; but if the eyes be darkened so effectually as to admit no light, the spots are not seen. Some years ago, I obtained a number of opaque lenses, extracted by Mr. Bader of Guy's Hospital, as I conceived that bile, or some of its constituents, was the cause of the opacity, and not blood. I took these to Dr. Letheby, and explained to him my reasons. He said, "If it is bile, we shall have a violet colour." The test was applied, and the violet colour was apparent to both of us. Upon this, I felt I was right in my opinion as to the cause of opacity in the lens. About the same time, I saw in a patient of Mr. Crichton, at Moorfields, the anterior chamber of both eyes filled with cholesteroline crystals, giving somewhat the appearance of the liqueur called "gold-wasser". The play of light on the crystals was remarkably beautiful. Now, what was the chemistry that separates these crystals from the bile in the aqueous humour? If cholesteroline crystals can be thus separated, why not some of the other innumerable constituents of the bile by the same wonderful chemical means, of which the microscope can give us no information? Why does the physician look at the conjunctiva for the yellow tinge, and then prescribe a blue pill and black draught, which sends all these phantom spectra to the winds? I therefore contend that bile, or some of its products, is the cause of the majority of muscæ; that all the tissues of the eye may be stained permanently or transiently, as fixed or fleeting muscæ. Even the retina, optic nerve, and I main are invaded by this subtle element, producing in the latter organ melancholia and symptoms of insanity. Donders says that in the vitreous humour of every one small microscopic bodies float: also for seventeen years a pearly string had existed in his right eye. He also talks of "coherent groups of little circles of various sizes—some pale, some dark; and membranes which terminate in irregular points—some torn off in rays, plates, pearl-spots, etc.; groups of scotomata, ordinary corpuscles, too small to be ophthalmoscopically visible". Does not all this give the idea of a crystalline formation too microscopic for our senses? I think in the bile Dr. Holland will find the "material archetype" for these formations. I cannot agree with him that true muscæ never spontaneously disappear; I had such in my right eye for twenty years. On leaving off wine, beer, and spirits, as well as pickles, cheese, and pastry, for a period of eighteen months, my permanent friends have taken their departure, but will rehabilitate themselves on a return to former habits. I think if "Medicus" will take this hint, and not resort to a silly evacuation of the aqueous humour, he will find the suggestion he asks for.—I am, sir, yours truly,

May 25th, 1878.

W. STORV.

SIR,—Having demonstrated in a former letter my theory of the formation of muscæ volitantes proper, will you allow me to call attention to what I believe are phenomena either directly dependent or consequent on the above affection. They consist of numerous specks—some dark-coloured, others bright, like the sparks produced in the discharging of a Leyden jar, which I become conscious of under exactly the same circumstances as the muscæ proper. I have been induced to consider them as a part of muscæ by their appearing always under exactly the same circumstances, and because they are seldom (in my case at least) long separated the one from the other. My explanation is this: they are produced from distension of the more minute capillaries of the retina by blood; and my reason for arriving at this conclusion is, that they generally appear in great numbers after exertion, or when the heart is strongly acting.

Any better explanation of their origin would greatly oblige yours, etc.,

F. R. GREENWOOD, M.R.C.S.

St. Bartholomew's Hospital, May 27th, 1878.

# NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

## UNQUALIFIED ASSISTANTS.

SIR,—It was much interest that I read the letter of "Undergraduate" in the JOURNAL of May 15th, as I believe it represents one of a comparatively select few of the great mass of unqualified assistants. These last are a class of men for whom, as a rule, I have little or no sympathy, many of them being students who leave at the time when more or less brought up with every advantage, have perhaps finished their curriculum, and had every opportunity for studying, so as to enable them to qualify and become members of an honourable profession; but they have chosen to throw them away, have neglected their studies, lectures, and work generally. Here and there, indeed, you may find one who retraces his steps, and, by a fixed determination to amend, under favourable circumstances, passes the portal and enters the profession a sadder but wiser man. Again, there are some men who never intend to qualify, who never work with that view. With such I have nothing to do; they deserve whatever fate befalls them; and should they some day find that the law causes their vocation to be gone, it is only what they can expect. All these are the men who bring discredit on the calling of the medical assistant, together with those medical men who willingly delegate their duties to them. But that the unqualified assistant should be condemned entirely, is, to say the least, as uncharitable as it is inconsistent. There are exceptions, of whom I hope and believe, "Undergraduate" is a type, who are worthy of the utmost consideration and sympathy—men for whom we should have the keenest desire to see helped and encouraged in their path, beset with many difficulties of no ordinary degree—men who have been diligent pupils, doing their best to obtain a sound knowledge of their profession, but who find themselves unexpectedly, by force of circumstances, misfortune, or some calamity, thrown upon life's battle before they have finished their curriculum, or enabled to pass all or any of their examinations. With these should be classed those students who are friendless and without means, who have never had the opportunity to qualify, but, wishing to enter the profession, and having no help but their own exertions, are undergoing many privations, endeavouring step by step to reach the goal and enter the portal by sheer hard work, extending over a long time. All honour due to such men, who often turn out our brightest and most learned examples, but, too often, at great cost of time and health. All these men who make assistants of undoubted value, as they possess those qualities most to be desired in an assistant. They are not unqualified because they wish it, but by virtue of their inability to obtain the necessary means; and all sensible well-thinking people could not be so unjust and cruel as to wish to deprive them of the only means they have of getting a living. There are few men, perhaps, that have less sympathy for the mass of unqualified assistants than myself; but there are exceptions, such as I have pointed out, for whom I have the warmest good wishes. I believe much might be done for the good of such men as "Undergraduate" and others, were the matter taken up by some eminent members of our profession.

I am afraid I have trespassed too much on your valuable space, but I trust and believe that you will, in common justice to the deserving unqualified assistants, give publication to this letter, as my object has been to show that they are not all such unworthy dogs as some would have us think.—I am, sir, yours obediently,  
May 15th, 1878. ANTI-HUMBUR.

J. W. I. V.—The address of Mr. Wickham Barnes, Honorary Secretary of the Poor-Law Medical Officers' Association, is No. 3, Bolt Court, Fleet Street.

## SUPERSTITION.

SIR,—There are sundry superstitions still abroad which, as they adversely influence some patients and their attendants, may deserve notice in the JOURNAL, with a view to giving medical men a cue for their abolition. That to which I especially now allude is the superstition relative to the "death-watch". Scientific men commonly affirm that the sound is caused by a beetle; but as it is sometimes heard where there are no beetles, people remain of their old opinion as to its supernatural origin.

About a fortnight ago, I heard a distinct ticking sound, exactly like that of a watch, and perfectly regular. It took some hunting to discover the cause, and at last I succeeded. A stone-jar of the usual pattern, with cork at one side and near the end, had been filled with very hot water the night before, and was in the morning standing on its end, nearly cold. There was, of course, a partial vacuum inside, and minute bubbles of air passing the cork and leaping through the water behind it caused the sound. It had been going on for fully half-an-hour, and stopped instantly on shifting the cork. To-day the same phenomenon occurred, and I called the servant's attention to it, and showed her how it stopped when the cork was moved. Now, if it happened that any one died in the house after a sound of this nature was heard, superstition would have been confirmed in the minds of the ignorant, who do not investigate causes; and in this instance it is not improbable, humbly speaking, that there might be a coincidence, since there are two invalids in the house, one suffering from a disorder about the heart. Hot-water bottles are so common in sick rooms, that I think the circumstance deserves noting.—Yours faithfully, C. L. B.

## COMPULSORY VACCINATION.

MR. JOHN BRIGHT has been visited rather severely by the medical journals for having, as they say, expressed himself in favour of selling indulgences to propagate small-pox. He holds that the payment of the first fine of twenty shillings should procure a regularity of parent immunity from further prosecution; "in other words, that every father could be at liberty to sacrifice the life of his children by omitting to protect them from the infection of small-pox, and to set up the foci of a dangerous and infectious disease on payment of twenty shillings". In calling this a most "pernicious and surprising doctrine", the BRITISH MEDICAL JOURNAL does not go one whit beyond the mark. Of two things one: either vaccination is useless, and then it ought not to be enforced by any fine at all, or it is a prophylactic against a most perilous and loathsome disease, and then it ought to be enforced even by imprisonment, just as one would enforce the law against the indiscriminate sale of poisons or explosives. To pass a law and then to contend that it may be broken for a sovereign, is to bring legislation and the legislature into contempt. There is no need to do that at a time when we are losing in London alone about eight lives a day through small-pox.—Western Morning News.

## OPEN SURGERY.

SIR,—Given an established practice, together with a fairly remunerative open retail, I should be glad if any professional brother, who has had practical experience in a similar case, would kindly give me an estimate of the probable result, financially, to a practitioner of average ability, of closing the latter.—I am, sir, yours respectfully, MEDICUS.

## REMOVAL OF THE TONGUE BY LIGATION.

SIR,—May I ask Mr. Fearnley, through the medium of the JOURNAL, to explain a paragraph in his letter of the 25th instant, in which he describes his mode of removing a tongue by immediate ligation? He says: "I have laterally transfixed the tongue with a blanket-pin, beginning at the right angle of the mouth and bringing it out at the left, and by this means carried the pin immediately in front of the epiglottis; I then placed a single loop of stout whipcord around the tongue, behind the pin", etc. What I wish to have explained here is, "the transfixion of the tongue with a blanket-pin". Why was this done? and will Mr. Fearnley also kindly tell me what a "blanket-pin" is? as I must confess to never having heard the term before.—Yours faithfully, A MEMBER.

## UTERINE HÆMORRHAGE.

SIR,—In the last JOURNAL (June 1st) I find a communication from Dr. D. Christie, describing his method of instantaneously arresting uterine hæmorrhage, than which nothing gives more anxiety to the medical attendant. After an active professional life extending over more than forty years, I must confess my ideas in connection with physics have become somewhat hazy; but before admitting the safety of the plan recommended, will Dr. Christie kindly state the cubical contents of the bag he introduces into the uterus, and the diameter of the seven-and-half feet tube connected with it?—Yours truly, G. H. FOSBROKE, Sen.  
Bridford, June 5th, 1878.

THE publication of the letter of "A Medical Sufferer" would lead to a theological controversy.

## PROFESSIONAL ADVERTISING.

SIR,—I beg to draw the attention of yourself and of the members of the British Medical Association to the enclosed circular, which has been extensively distributed in this neighbourhood. I observe Mr. James Kennedy is a member of the Association, and wish to have the opinion of his co-members regarding the production.—I am, etc., M. B.

Fraserburgh, N.B., June 1878.

"Mr. James Kennedy, Surgeon, desires to intimate to the inhabitants of this town and surrounding districts, that, at the suggestions of many friends and others, he will attend, professionally, families who pay him a yearly sum of ten shillings each—lying-in cases and medicines excepted. Lying-in cases from ten shillings and sixpence to one guinea each, according to the circumstances of families. Professional visits in town to non-subscribers, one shilling each visit. These terms shall hold good up to two miles from Surgeon Kennedy's residence; and beyond two miles, and up to four miles, lying-in cases attended for one to two guineas each, according to agreement. Country patients attended at moderate rates.—Roseheart, by Fraserburgh, Aberdeen, May 10th, 1878."

# LECTURES ON THE DIAGNOSIS AND SURGICAL TREATMENT OF ABDOMINAL TUMOURS.

*Delivered at the Royal College of Surgeons of England.*

BY

T. SPENCER WELLS, F.R.C.S.

Professor of Surgery and Pathology in the College; and Consulting Surgeon to the Samaritan Hospital.

## LECTURE II—June 12th, 1878.

*Semisolid Abdominal Tumours; Different Kinds of Ovarian Tumours—their Diagnosis—Complications with Pregnancy; Extra-uterine Pregnancy—Specimens illustrating various other Conditions resembling Ovarian Tumours; Fibroid and Fibro-cystic Uterine Tumours; Tumours of Abdominal Wall; Tumours of Omentum and Mesentery, of Liver, Spleen, Kidney, and Mesenteric Glands; Cancer and Tubercle; Aneurism; Hematocele and Pelvic Abscess; Fæcal Accumulation; Phantom Tumours.*

AT the lecture on Monday, I was speaking about the chemical qualities of the fluid removed in tapping ovarian cysts; and yesterday, I had an opportunity of removing from a young lady sixteen pints of fluid, of which this is a portion. You will see that it is very nearly of the colour of distilled water. Through this green bottle, there is a little tint visible; but if it be put into a white glass jar, there is no colour to be seen, only the very slightest opalescence. The specific gravity is 1006, which is a little more than we occasionally find in these fluids removed from simple cysts. Then the albumen which it contains is not true albumen, but the form I have described to you as being the coagulum which, formed by heat, is redissolved upon the addition of boiling acetic acid; so that the albumen is not true albumen but paralbumen. On examining the deposit, there is nothing whatever to be seen, and the fluid may be looked upon as a very fair or typical specimen of that from a simple or single ovarian cyst, or of an extra-ovarian cyst—a cyst formed in the broad ligament near one or other ovary. Yesterday, also, I had the opportunity of removing a single ovarian cyst; and thinking it might interest you to see it, I have brought it here. You will see what a very thin-walled cyst it is, completely single, absolutely free from all adhesions, and the only opening in it is that made by the trocar in emptying the fluid from it, in order that the empty cyst might follow the fluid removed. The case very well bears out what I was saying about the difficulty occasionally met with in ascertaining whether the fluid in a large cyst is really in a cyst or whether it is free in the peritoneal cavity. The lady was fifty-seven years of age. Last summer, the abdomen began to increase in size. She consulted two or three physicians, who all told her she had liver-disease and dropsy, but whether the dropsy depended on cancer or tubercle, they did not seem very well to know. Then Dr. Risdon Bennett, the President of the College of Physicians, saw her. He had no doubt at all about the fluid being encysted, and advised the patient to see me. I at once advised that she should be tapped, seeing that the cyst was a single cyst, and possibly it might be one of those cases in which the fluid would not re-form after tapping. I tapped it last October, and eighteen pints of fluid were removed. The lady improved very much in health, and went to Brighton. Last March, it was again tapped, about the same quantity of fluid being removed. It is a curious instance of the different reports one gets about the quantity of fluid removed. The surgeon who tapped her wrote to me that he removed "seven gallons of fluid". I thought it very strange, and on questioning the patient, I found instead of being seven gallons it was seven quarts. That is the kind of mistake one sometimes meets with inadvertently made in the reports of cases. After the second tapping, the cyst refilled; and as it seemed a case in which mere tapping would be of very little use, it was arranged I should remove the cyst yesterday, which I did, and here it is. It is a thin transparent cyst, which yesterday contained eighteen pints of fluid, and which came out through a very small opening as soon as it was emptied. As the fluid escaped, so the empty cyst came out. There is nothing more to be said, except that the patient is perfectly free from fever, and in all probability will do very well.

Then I was going on, at the close of the last lecture, to speak about the microscopical examination of the fluids removed by tapping, and I was about to show you some of these diagrams, which show the last additions to our knowledge on this question. Long ago, Dr. Hughes Bennett of Edinburgh described certain cells, which are extremely well figured in his little book—cells which he considered to be quite distinctive of the fluid removed from ovarian cysts. He believed that when those cells were found in fluid, it could come only from an ovarian cyst, and from nothing else. This examination was afterwards carried on, and in my own book on *Diseases of the Ovaries*, which I formerly mentioned to you, there are about one hundred figures, embracing nearly everything which had been described up to that time as having been found in cysts of various kinds. Mr. Nunn had previously described some of the same sort of granular cells or epithelial cells and granules; and then, in America, Dr. Drysdale, the son-in-law of Dr. Atlee of Philadelphia, having the opportunity of examining nearly all the cysts removed by Dr. Atlee, carried on this investigation, and described, as "ovarian granule-cells", the cells which are pretty well shown on this diagram—that sort of cell which differs very little from the cell which Dr. Bennett described years before as characteristic of the fluid of ovarian dropsy. I have also drawn here some ordinary red blood-corpuscles, in order that you might make the comparison of the size in which these things appear as compared with a blood-corpuscle under the field of the microscope. (Figs. 1 and 2.) We

Fig. 1.

Fig. 2.

suppose these to be simply the nuclei of the epithelial cells which line the interior of the cyst. The scales are thrown off, the cell-wall breaks down, and the nucleus remains.

After a good deal of controversy as to the exact meaning and value of these things, whether they are found in ovarian cysts only, or in the kidney, or the spleen, Mr. Knowsley Thornton, who for some time past has examined a great many of the tumours which I have removed, made a great addition to our knowledge in pointing out that, in addition to these cells of Drysdale, which are common only in simple or innocent ovarian tumours, in malignant tumours you have these very characteristic groups of cells of different sizes. He describes them as large numbers of characteristic groups of large pear-shaped, round, or oval cells, containing a granular material with one or several large clear nuclei, with nucleoli and a number of transparent globules or vacuoles. The cells composing the groups are many of them very large, but the great variety in size and shape is the marked feature of the group. If you will bear these different forms in mind, and these different cells, I believe you will find that they are characteristic, and of great value in the examination of these fluids, putting us on our guard when we have to deal with tumours doubtfully malignant. If these large groups of cells be seen, one may be pretty certain the tumour is malignant of some kind; or if they be found in fluid removed from the peritoneal cavity, probably a sort of infecting process has been going on in the peritoneum from the rupture of an ovarian cyst of a malignant character; these cells may have planted themselves upon some part of the peritoneum and multiplied.

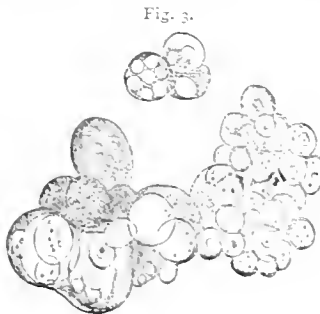

Fig. 3.

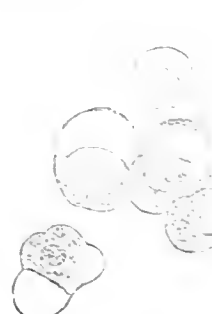

Fig. 4.

the pancreas, omentum, etc., freshly drawn and no reagents used. In fig. 5 are single cells and groups from the sediment of peritoneal fluid treated with nitric acid and logwood. The single cells show the vacuole substance (colloid) pressed to the outer surface by the action of the reagents. The centre cell in the group shows the colloid substance shrivelled from the same cause. The case was one of slow-growing sarcoma of the ovary. Figs. 6, 7, and 8 represent cell-groups

Fig. 6.

Fig. 7.

Fig. 8.

and a single cell from the same fluid as No. 4, but treated with nitrate of silver. There are vacuoles both in the cells and nuclei; in the cells pressed to the circumference by the action of the reagent. The single cell has the characteristic balloon shape, and shows a curious row of nuclei. Fig. 9 gives a view of a group of cells from peritoneal

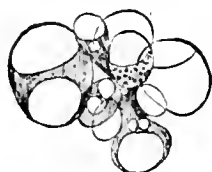

Fig. 9.

fluid (fresh, no reagent used) in a case of rapidly growing sarcoma of ovaries and uterus. The nuclei have all disappeared, and the cells are almost destroyed by vacuolation. All these drawings were made for me by Mr. Thornton himself.

This last drawing (fig. 10) shows Dr. Drysdale's sketch of the fluid

Fig. 10.

removed in a case of fibro-cystic tumour of the uterus, with what he calls "fibre-cells". I need not say more now about the microscopical appearances found in these fluids. The work of Dr. Atlee, with Dr. Drysdale's own illustrations, is very well known, and may be found in the library.

I think, before passing on to speak of the different varieties of semi-solid tumours, ovarian tumours and others, I will just draw attention to this very large cyst of the left kidney which I removed during life; and close beside it is the uterus from the same patient, showing the ligature which has been placed on one of the ureters, and also showing that in the cavity of the uterus there is a polypus. That is one of the points in which we were led wrong in the diagnosis of the case. The patient was a woman 29 years of age, the wife of an agricultural labourer. She was sent to me from Yorkshire, and was stated to have had an ovarian tumour for some years, and to have been tapped several times. I found that there were cicatrices of the tapping punctures in front of the abdomen, and that the abdomen was distended by this very large cyst. The uterus was large, and it was difficult to make out what the exact connection between the tumour and the uterus was. I do not think anybody who saw the case had any doubt that it was an ovarian cyst; the only question in the case was whether or not the woman was pregnant, and I proceeded to the operation without the faintest shadow of a doubt that I was going to remove an ovarian cyst. But, as soon

as the abdominal wall was divided, I found I was coming upon something peculiar. I could not find the peritoneum as one generally does, but came rather upon the cyst-wall covered with a loose layer of cellular tissue, and I then began to think I was dealing with an extra ovarian cyst, the sort of cyst one often finds covered by an expansion of one or other of the broad ligaments; so I emptied the cyst, expecting to be able to separate it more easily. When it was empty, I began to try to separate the adhesions. I found the uterus and both ovaries quite healthy, and then, of course, came the question of what should be done. I was disposed to leave it alone, and see what drainage would effect; but so many adhesions had been separated, that that seemed to be rather hazardous; and, although I perceived it was a kidney-cyst, I thought I had better remove it, and so I did. I tied the vessels, and the operation seemed to have been completed satisfactorily. The tumour was removed, and there was no very great loss of blood. The patient was put to bed, and for some time looked as if she were likely to go on pretty well; but, on the fourth day, she died, without any very characteristic symptoms having been observed. There was nothing peculiar in the urine, and nothing more than one commonly sees in cases of ovariectomy where the patient gets some amount of fever after the operation. On examining the tumour, it is seen very distinctly that the kidney has been expanded, as it were, into that large cyst. I thought it might be interesting to bring this specimen under your notice, as showing that we may get very large single cysts simulating ovarian cysts; and that, when they are associated with a large uterus and with a history of ovarian fluid having been removed at previous tapplings, it would take a great deal of care indeed to avoid this sort of error.

The case leads me to speak of another which was somewhat similar, in which we did not make a mistake in diagnosis. A certain amount of pointing in the right loin led to a more careful examination of the state of the case, and making an opening into the loin, introducing a drainage-tube, and treating it antiseptically, keeping the end of the tube covered with a sponge wetted with carbolic acid and occasionally injecting, that patient was completely cured. I do not think the tumour was so large as the first, but still it did contain a very large quantity of fluid, and fluid which, singularly enough, had a great deal of cholesterine in it. I do not think this has been previously noticed in renal cysts. I will not say more about renal cysts at present, and will proceed in the order which I have laid down in the printed prospectus of these lectures to speak of the semisolid abdominal tumours which one may meet with in great variety. Of these we have several specimens on the table.

Here are four very good specimens of encysted tumours. I will just say a word about the different kinds of ovarian tumour, passing on from the simple single kind which is there. Here is a very good specimen of the multilocular form, which has been very well injected, showing the arrangement of the vessels of the walls of the cyst; and here is an interesting specimen of a cyst in the ovary from a child only five weeks old. Oddly enough, there were twins; one died at five weeks and one at seven weeks, and they both had ovarian cysts. There was nothing wrong about the mother, who was a healthy woman.

Solid tumours in the ovary are much more rare than semisolid ones, but here is a good specimen of a solid tumour which I removed some years ago from a young lady nineteen or twenty years of age, a patient of Mr. Prescott Hewett—a case of perfectly characteristic soft cancer of the ovary. She went on well at first; but, a day or two after the stitches were removed, there was a partial reopening of the wound, accidentally caused by coughing; peritonitis followed, and death. I do not suppose the patient would have ultimately recovered after such a character of growth as that; but still there would have been a temporary recovery, had it not been for that accidental occurrence.

The different kinds of ovarian tumours and the diagnosis of adhesion may be made out by some little attention in the examination of a patient. We can ascertain with a little care whether a cyst is a single cyst with limpid contents, or whether the contents are likely to be viscid, and this will assist us in forming some opinion as to whether one should be content with tapping and drainage, or whether it would probably be ultimately necessary to resort to ovariectomy. The reasons which would induce us to suppose that the cyst is single, and that it probably may be cured by tapping, are that it may have existed for many years without any great effect upon the general health of the patient; or, on the other hand, that it has formed with such extreme rapidity that it is almost certainly mistaken for ascites. You see a young woman whose abdomen has rapidly enlarged (one may sometimes see this one's self, but it is more frequently reported); but I saw it in the case of a young lady I examined many years ago with Dr. Rigby. Neither Dr. Rigby nor I was at first certain that we could

discover anything in the abdomen; we thought we could make out a little dulness and doubtful fluctuation, but there was no enlargement, and yet, in three weeks, that cyst was as large as an adult head. It rapidly increased, and had to be removed in three weeks after the first examination. That is a very rare and exceptional case. When you get this very rapid formation of a cyst, it is pretty certain the cyst is a single one; and so also if the cyst have existed a good many years, and the patient have not suffered much from it, it is probably single; and these are cases in which tapping alone may not only afford temporary relief to the patient, as it does, but may possibly complete the cure; the fluid may never re-form. In such a case as this, one can detect no hardening of the cyst wall, no nodules, and the surface is so smooth one can make up one's mind that there are no groups of secondary cysts about it, and that it is practically unilocular. When you get resistance to the wave of fluctuation in different directions, then you may also be pretty certain that there are septa dividing the cyst into different portions, and that it is of a multilocular character, and in that case tapping would be of no use; although one compartment might be emptied, the others would remain full. Supposing we find cartilaginous or hard bony projections, or nodules, in different parts of the cyst, then the probability is strong that the tumour is one of the forms of dermoid tumour, in which we may find cartilage, bone, fat, hair, teeth, and other things, of which we have some good specimens in the museum. Occasionally one begins to doubt whether both ovaries are affected or not. We may meet with a sulcus going immediately down the abdomen, and, if we find intestine there, in that case it is extremely probable both ovaries are affected. Sometimes this is deceptive. I have seen a very large sulcus on the surface of one ovarian tumour, made by the Fallopian tube pressing it in the centre, so that there was a very distinct bulge on either side, and we felt almost certain that both ovaries were affected, whereas only one was diseased. The belief of Boinet, that one can foretell before tapping the character and colour and consistence of the fluid, has a certain amount of foundation. The progress of the disease, the more or less acute pain complained of, the other signs of inflammation more or less rapid, and the state of the general health of the patient, will lead to suspicion probably that one has some purulent fluid, or mixture of blood and serum, or pus in a cyst; if there have been a rise of temperature at night, loss of appetite, and other signs of fever, you may be pretty certain there has been some inflammatory change going on in the substance of the tumour or cyst, which will lead to changes in the condition and character of the fluid.

The solid tumours I need not say anything more about, except that they do not fluctuate; they are solid. These are much rarer than cases where one finds a portion of the tumour solid and a portion of it fluctuating.

Then with regard to the diagnosis of adhesions, it used to be thought a matter of very great consequence to determine, before undertaking to remove an ovarian tumour, whether it was adherent or not; and, in the early days of ovariectomy, great trouble used to be taken by Dr. Frederic Bird and others to ascertain, if they could, whether the tumour was free. They would tap and watch carefully the way the cannula moved as the cyst emptied, and Dr. Bird used to put needles through the abdominal wall into the cyst, to see the way in which the ends of the needles were deflected, and, if there were signs that the cyst was adherent, then it was not considered a case in which ovariectomy ought to be attempted. When I commenced practice in this particular department of surgery, I soon began to doubt whether this was a point of much consequence, and, when one began to number cases by hundreds, there seemed to be very little difference in result between cases of adhesion and of non-adhesion, so that I do not think we need give more time or attention to this point, but it is as well to remind you of it.

I have here some specimens of bone and teeth, from cysts which I removed, prepared by Dr. Junker, who for five years was in Japan teaching the Japanese surgery, establishing a surgical school there, and carrying the benefits of our surgical knowledge to the Japanese. They illustrate extremely well the forms of bone-like matter which one occasionally meets with in dermoid cysts of the ovary.

To revert for a moment to the subject of diagnosis of adhesions: practically, I think, the question of extent of adhesion to the abdominal wall is not of much consequence. The result is pretty much the same, so far as the adhesions go, to the patient; but the amount and intimacy of pelvic adhesions are matters of very much greater moment. Supposing an ovarian cyst is adherent low down in the pelvis, between the uterus and rectum or the uterus and bladder, or on either side, the attempt to separate it is necessarily a dangerous one. If any blood-vessels be torn, it is difficult to find them. Although by artificial means one can occasionally throw a strong ray of light to the bottom of the pelvis and secure a bleeding vessel, yet it is troublesome and difficult to do; and the results of these cases are by no means so satis-

factory as when there are only adhesions to the abdominal wall. One can pretty well ascertain if there be such adhesions as these, by a careful examination of the pelvis by the vagina, whether the uterus is fixed to a portion of the tumour. You find that they do not move with the position of the patient; they do not move when she coughs; they do not move when the shoulders are lowered and the hips raised; and it is impossible, either with the uterine sound or in any other way, to separate the uterus from these pelvic portions of the adherent tumours. Occasionally there will be an ovarian tumour low down in the pelvis which does move, from which the uterus can be separated, and need not interfere at all with ovariectomy; and in such cases it is sometimes quite curious to hear the rush of air into the bottom of the pelvis when the lower portion of the cyst is separated from the hollow of the sacrum. Air rushes down with a gurgle, the tumour is easily brought up, and there is no more difficulty than in an ordinary case. It occasionally becomes very doubtful whether an ovarian tumour is simply jammed down into the pelvis, or whether it is fixed there by strong adhesion; but still I think this can be made out by care—ascertaining whether the uterus is movable; ascertaining whether the lower portion of the cyst moves in different positions of the patient; and, if it really be firmly fixed, whether the sensation to the finger is that it has been absolutely glued down to the bottom of the pelvis. If there be this intimate adhesion pretty low down, as a rule I think the operation is not one that is likely to succeed.

The specimens on the table illustrate extremely well a number of conditions which may be mistaken for ovarian tumours, and which frequently are mistaken for them. The fibroid and fibro-cystic uterine tumours are those which are most commonly mistaken, and there will be other specimens of this kind brought down at the last lecture; but there is one here which is a specimen of a case of very great interest, in which Mr. Adams removed an extra-uterine foetus from the abdomen. Here is another, in which a foetus was retained for fifty-two years in the abdomen. I do not suppose either of these cases would have been mistaken for an ovarian tumour; but still, in calculating what one may meet with, it is well to bear in mind that that sort of thing may exist. In the last lecture, we will have other specimens of fibroid and fibro-cystic tumours of the uterus brought down, to show how closely some of them resemble ovarian tumours and what a large size some of them attain. Here is a very beautiful specimen of melanosis of the ovary—a specimen not often seen. Here are tumours of the spleen. This is a spleen which I removed during the life of the patient; it weighed nine pounds, and the patient lived seven days. The case I need not go into further. In two other cases, I removed the spleen just about the same size; but in neither of the three did the patient survive. There was only one that died from hemorrhage; in the other two, there was no hemorrhage, nor much peritonitis; but there was a quantity of white clot on the right side of the heart, which seemed to be the cause of death. The diagnosis was made out with great ease in those cases. One was a case of Sir William Jenner's, in which he made out disease of the spleen as having existed some long time before. There was some alteration in the white blood-corpuscles; but Sir William Jenner thought it was a case in which one might very fairly and reasonably remove the spleen, and the patient seemed to be extremely likely to recover. She went on well for seven days; and at the end of the seventh day, without any reason that one could see, she died quite suddenly. But the reason was manifest after death: there was a very large clot on the right side of the heart.

Here are numerous cases of cancer in different parts of the abdomen; and these varieties of malignant disease in the abdomen lead very often to mistakes with regard to ovarian tumours. There have been a great many cases of attempted ovariectomy where no ovarian disease at all has been found, but the tumour has proved to be cancer of some one or other of the organs of the abdomen—the liver, for instance. Here are cases of liver-disease and disease of the omentum which have led to distinct mistakes. Here is a case of disease of a portion of the omentum which was mistaken for pregnancy. After death, it was found out that there was disease of the omentum, of which this is a portion. Here is a case of enlarged liver. Here is a case of dropsy of the gall-bladder; this of course, if larger, would make a considerable tumour; and many of you will, perhaps, read with interest next week the continuation of a paper begun by Dr. Marion Sims last week in the BRITISH MEDICAL JOURNAL, in which he relates how he opened the gall-bladder, sewed the opening to the wound in the abdominal wall, and turned out a very large number of gall-stones. I once had an operation considered in consultation about a patient in Kentish Town who had a very large tumour, and the great probability was that there were gall-stones; but there was also evidence that there was malignant disease of the liver, and nothing was done. I am afraid to say the number of gall-stones that were found after her death, but I

think one thousand eight hundred; and beside that the gall-bladder was very much thickened by cancer. Here is a specimen of cancer of the liver which would have made a very large tumour; there is one of melanosis of the liver. Here is one of tubercle of the liver—a very rare specimen; and here is one of hydatid of the spleen. These hydatid cysts occasionally lead to mistakes. In my work on *Diseases of the Ovaries*, there is a picture of a woman taken from a photograph, from whom I removed successfully a very large hydatid cyst which we had correctly diagnosed after tapping. The limpid fluid removed at once attracted attention. I examined the deposit, and found it characteristic of hydatid disease; so, after a time, as the woman seemed to be likely to die, I removed the hydatid cyst. She completely recovered.

Aneurism occasionally may be met with. Here are one or two good specimens of aneurism of the aorta. It is not likely that aneurism of the abdominal aorta will be mistaken for an ovarian tumour, but still it is well to bear this in mind. I know of one case in which an aneurism of the aorta lay down, just where it bifurcates, was tapped through the vagina, believing it to be a pelvic abscess. That lady died upon the table in a very few minutes. So it is just as well to remember that these large aneurisms of the abdominal aorta should be considered in forming one's diagnosis.

With regard to hæmatocele and pelvic abscess, I need not say much here, except to put younger men upon their guard to remember these do form occasionally of so large a size as to be mistaken for ovarian or other tumours. I have seen a hæmatocele extend considerably above the level of the umbilicus, and a pelvic abscess almost as large.

Fæcal accumulation, too, but rarely leads to error. Occasionally one is called in to cases where accumulations of large quantities of feces do lead to mistake, and the supposed tumour disappears after their removal.

Then, a word as to those resonant enlargements of the abdomen which have been called phantom tumours. There is now in the Samaritan Hospital a young woman with an apparently manifest abdominal tumour. The abdomen was prominent, and felt hard; but, on percussion, was distinctly resonant everywhere. She looked in perfectly good health, and, on putting her under the influence of chloroform, the swelling entirely disappeared. There has been a certain amount of doubt as to the exact pathology of these things, whether it is that the diaphragm is pressed downwards, the liver pressed forwards, and a certain amount of distension of the intestines accompanies the arching forwards of the recti; but certainly occasionally they do look very much like tumours which disappear entirely when the patient is deeply narcotised. I have seen the same thing in a man. I remember a soldier came down to Smyrna from the Crimea with a tumour which excited a good deal of attention amongst the surgeons at Smyrna, but, on putting the man under the influence of chloroform, it entirely disappeared.

With regard to pregnancy, the ordinary signs of pregnancy, of course, should be borne in mind in any case of abdominal tumour in a woman. Whether the woman is single, or married, or a widow, this complication may arise. I need not enter into the different signs of pregnancy; but I wish you to bear in mind that not only may pregnancy be mistaken for ovarian disease, or uterine disease, or the converse, but that in many cases pregnancy does complicate ovarian disease. A woman may have a large ovarian tumour, and then she may become pregnant; and the question of the treatment of a woman who has an ovarian tumour and is also pregnant is one I shall have to speak of when I have said something about ovariectomy.

I do not think there is a specimen here, I doubt whether there is in the Museum, of what is called "movable kidney". I believe there have been only one or two such specimens shown after death at the Pathological Society, but I have occasionally seen tumours in the abdomen which appeared, as far as one could tell, to be instances of movable kidneys, either enlarged or of their natural size. One case was such a remarkable one that I will detain you a moment to tell you about it. A lady came to me believing she had, or having been told she had, a movable right kidney. I saw her with Dr. Wilson Fox, and we both agreed that that was the nature of the disease. For some years it went on, and I saw her occasionally, under the impression that she was suffering from a movable kidney. Then she became pregnant, and pregnancy went on to its natural termination, and a healthy child was born. Soon afterwards, she began to suffer from an ovarian cyst on the left side, the movable kidney still being on the right side; and the ovarian cyst increased so much that it was decided I should perform ovariectomy, which I did. I said at the time "I will see what that movable kidney is now"; and, after I had removed the ovarian cyst on the left side, I felt what the supposed kidney was, and took it out; and then I found it was the right ovary, but it was attached by a pedicle

fully a foot long. It had been held up under the right false ribs by the merest little film of adhesion. Quite a small patch of adhesion kept this right ovary, which was about the size of my fist and very much of the shape of a kidney, just in the position of a movable kidney. The patient recovered, and remained in good health.

Then, as to cancer of the ovary. Here are some specimens. Here is cancer of the ovary; and here is cancer of the kidney. There is a specimen also of a tumour of the abdominal wall. This illustrates a mistake occasionally made in practice: in the treatment of a supposed abdominal tumour, it is found that the tumour is not of the abdomen at all, but is simply a tumour of the abdominal wall. I remember years ago being called to see a patient, who came from Portugal, supposed to have ovarian tumour, and I expressed a strong opinion that it was not ovarian, but simply a tumour of the abdominal wall, and decided that it should be left alone; but Mr. Baker Brown afterwards saw the patient, and removed it. He removed a very large portion of the abdominal wall with it. He removed a bit of the peritoneum as large as the palm of my hand, and yet the patient made a most complete recovery. The tumour was a fibro-plastic tumour of the abdominal wall of a considerable size, and the portion of the abdominal wall removed with it was two or three inches in breadth and three or four in length. Yet the abdominal wall, which was brought together without much tension, healed up, and the woman recovered almost as well as if the operation had been one of the most simple character.

### THE POLYURIA OF GRANULAR KIDNEY.

By GEORGE JOHNSON, M.D., F.R.S.,

Professor of Clinical Medicine; Senior Physician to King's College Hospital; etc.

HAVING neither time nor inclination for a controversy on the above subject, I am nevertheless anxious not to be misunderstood. In my paper in the JOURNAL of May 25th, I expressed my dissent from the theory which assumes that the copious secretion of urine by a granular kidney is the result of increased pressure on the Malpighian capillaries consequent on obstruction in the intertubular capillaries. I maintain that this theory is utterly inadequate to explain the phenomena, and that the attempt to give them this merely mechanical explanation tends to mislead and retard the progress of actual knowledge. I believe, too, that the results of the impeded renal circulation consequent on cardiac disease are fairly comparable with those which would follow upon an intertubular capillary obstruction. The results in both cases would be, of course, a general diminution of the blood-current through the kidney, a gradual increase of pressure on the Malpighian capillaries, a scanty secretion of water, and ultimately a more or less copious transudation of albumen into the uriniferous tubes. These are the phenomena which are commonly observed in cases of large Bright's kidney, when the swollen uriniferous tubes compress the intertubular plexus, and thus cause a backward strain upon the Malpighian capillaries.

It is to be borne in mind that there is no relation whatever between increased pressure on the Malpighian capillaries consequent on an obstruction in front and such increase of pressure as may result from relaxation of the afferent arterioles. It is to the latter phenomenon that reference is made by Dr. M. Foster in the chapter of his *Text-Book of Physiology* to which Dr. Saundby directs attention, and this phenomenon is not now in question. While I believe that no trustworthy inference can be drawn from such an experiment as that of Dr. Grützner to which Dr. Saundby refers, I feel called upon to correct the erroneous assumption that the contraction of the hypertrophied muscular arterioles must render the kidney anæmic. Dr. Saundby, in raising this objection, overlooks the fact that the resistance offered by the arterioles is more or less completely counterbalanced by the increased injecting force of the hypertrophied left ventricle. And, again, it is not to be supposed that the renal arterioles are in a constant state of extreme contraction, or that their muscular walls, even in the advanced stages of a granular kidney, are beyond the control of the vaso-motor nervous influence by which circulation and secretion are co-ordinated. We may reasonably suppose that, while the regulating influence of the hypertrophied afferent arterioles prevents undue strain upon the Malpighian capillaries from the injecting force of the strong left ventricle, "there is no shutting off of the blood from the glomeruli", but the blood-supply to the gland is sufficient for the purposes of secretion to any amount.

## ON THE WORKING OF THE VACCINATION LAWS.\*

By EDWARD CATOR SEATON, M.D., F.R.C.P.,  
Medical Officer to the Local Government Board, etc.

THE subject on which, Mr. President, you have requested me to speak this evening is the Working of the Vaccination Laws; and to that subject I shall strictly confine myself.

Compulsory vaccination in England dates from a quarter of a century ago, and the law has in that time passed, if I may so say, through three stages. The first Act, passed in 1853, directed, under penalty, the vaccination of infants at an early age; without, however, designating the local authorities who should put the law in force or the sources from which the expenses of so doing were to come, and without providing any adequate machinery of registration. By a short Act, passed in 1861, power was given to boards of guardians to pay out of the poor-rates for prosecutions undertaken under the Act of 1853, and to appoint persons to prosecute; otherwise the law underwent no considerable change till 1867. It was in that year enacted that boards of guardians not only *might*, but *must*, see the law enforced; the power, however, to employ officers specially for the purpose being still left permissive. A workable machinery for the registration of successful vaccination was then for the first time provided. In 1871, the law took its present shape. The employment of vaccination officers in every union was then made obligatory, and these officers were subjected to instructions to be issued by the Local Government Board. Further improvements were made in the machinery for registering vaccination and in other details.

Each of these measures was attended with a great degree of success. The Act of 1853 produced immediately a considerable increase in the amount of vaccination done in the kingdom, though, from want of a proper registration machinery, it is impossible to say exactly *what* increase; and it produced also this most important result—that, whereas before its enactment the vaccination of children had been left as often as not till they were above a year old, vaccination from that time forth was, and has continued to be, habitually performed in early infancy. It was to the representations of the Epidemiological Society, who insisted on the serious consequences arising from procrastination, and who called prominent attention to the fact that one-fourth of all the deaths from small-pox in England which occurred at that time were in children under one year old, that this great improvement was chiefly due. Systematic practical working of the compulsory law, however, only began with the Act of 1867; and the results of the power—which had been given, indeed, in 1861, but which had only come practically into use under the Act of 1867—to local authorities to appoint special officers for the purpose of this working, were soon seen so remarkably in the places where these appointments had been made, that the Parliamentary Committee, which sat in 1871 to inquire into the operation of the Act of 1867, did not hesitate to recommend that the appointment of such officers be made universal throughout the kingdom. This was done in the Act (passed in 1871) on that Committee's Report.

Since this last Act has come into operation, we have been able to know exactly how we stand with regard to the vaccination of our infantile population. From the beginning of January 1872—*i.e.*, for the last six years and upwards—there has been a regular registration of the vaccination of all infants whose births had been registered, and the result is put annually before you in the Report of the Local Government Board, showing that all registered births are within 5 per cent. accounted for, and finally accounted for, in respect of vaccination; more than 95 per cent. being entered in the registers either as having been successfully vaccinated or as having died in infancy without vaccination. The 5 per cent. which remains includes the temporary entries in the vaccination-register as of the children whose vaccination was, at the time of the return, postponed on medical certificate; it must include many cases actually vaccinated, though the vaccination certificate has not been transmitted to the vaccination officer; it must include many who have died in districts other than those in which the births had been registered, the death not having been notified to the vaccination officer of the district last named. The proportion, therefore, remaining alive and actually unvaccinated, and endangering the community by their want of vaccination, must be very much smaller than the 5 per cent. here indicated.

This account must surely be regarded as highly satisfactory. But is it wholly so? By no means; for the result I have been giving you is the result for the kingdom at large—the average of all the districts,

good, bad, or indifferent, as the case may be. There are whole counties, and there are large and important towns, which account for all their births within 2 per cent. or less; there are others where the deficiencies are 6 and 7 per cent. There is this vast metropolis, which, if we take it as a whole, is simply, I am sorry to say, the worst in England, the deficiencies amounting to 8.8 per cent. There is, therefore, a task remaining to be accomplished; *viz.* to bring up the bad districts to the standard of the good. Not that it is possible to have the same standard for all classes of districts. To expect it would be most unfair. It is not for a moment to be supposed that, in towns like London or Birmingham, children can be traced as easily as they can in, say Hertfordshire or Bedfordshire; or that even large towns may not present important differences one from the other, specially as to the migratoriness of their respective populations; but differences so considerable as those to which I have had to refer as existing between London and some of our large towns, as, for example, Leeds and many of the large and populous towns of Lancashire, in which the proportion of births annually unaccounted for is brought within 2 per cent., are not to be accounted for by mere difference in the habits of the population. In London itself, the results in different unions have been found to differ greatly. The great facility of passing from district to district in the metropolis interposes unusual obstacles, indeed, to the ready working of the Vaccination Acts, and necessitates an extraordinary degree of promptitude and vigilance on the part of the vaccination officers; and of these officers personally there is, I believe, in general, little or nothing to complain. Some of them are, I know, officers of great excellence; but I fear there are not enough of them for the vast amount of work to be done. There are in London but thirty-six officers altogether—a force which, relatively to the amount of births to be looked after, is, even apart from the existence of special difficulties, when compared with the force employed in the rest of the kingdom, very small. Hence the requirements of the instructions given to the vaccination officers to look up each case in default *as soon as the default arises*—*i.e.*, as soon as a child has passed three months of age without vaccination—cannot in London be fully carried out. Frequently children are not inquired about till they are six or seven months old, and thus the mass of unvaccinated children is unduly swollen. Moreover, in the interval, it not unfrequently happens that removal has taken place and the children cannot be found at all. Such defects, then, and others which may exist in particular districts, require correction before we can be completely satisfied with the present working of the law. They are, so far as they occur, defects, not of the law itself, but of its local administration.

And now with regard to the extent to which we may expect that these compulsory provisions of the law, properly carried out, will give us protection, present and future, against small-pox. It is of great importance that these expectations should not be exaggerated. In the first place, it will be seen that the law does not make vaccination universal; it cannot do so. Children are born every day, and I do not believe that any attempt to diminish the time allowed them for primary vaccination would be tolerated. There must always, then, be a stock, which even in large towns would be at the least a three months' stock, and in rural districts a larger proportional stock, of unprotected babies inevitably on hand; for, if many infants are vaccinated, as we know they are, *before* the expiration of the legal period of delay, there are more who are allowed to go somewhat beyond that period before the vaccination is performed. Besides these, we must have, as endangering us for the while, the postponed cases. Then we have, as a more permanent danger, the cases called insusceptible (quite unprotected, as I need not say, against small-pox), happily not many, and, so far as they exist at all, an opprobrium to us. And, lastly, we have the cases—destined, I hope, to become fewer and fewer every year, but of which we must always have some—who escape our notice altogether. The actual number of births hitherto unaccounted for annually in England and Wales has been about thirty-five thousand, of which no fewer than nine thousand have been in London alone. These are by no means, as I have explained, all living and unvaccinated; but there are more than enough of them who are so, fully to account for the six hundred deaths and upwards from small-pox which have occurred between one and five years of age in the present epidemic of that disease in the metropolis.

As to actual protection at the present moment of the population of England by vaccination, we must remember that we have no exact knowledge of that portion of them which is over six years of age.

Second only in importance to the necessity for the vaccination of all children at as early an age as can be effected, as a safeguard to the country against small-pox, is that of having them all thoroughly vaccinated. This is a point on which, I cannot doubt, all here present are agreed. The "due and efficient" performance of the vaccination

\* Read before the Metropolitan Counties Branch.

was a cardinal point with Jenner, insisted on by him throughout his writings; but researches made and experience acquired since his time have extended the meaning of these words beyond that which Jenner attached to them, and have given us a standard of success which we must be careful to observe. I cannot but think it a great cause for gratitude, that the magnificent and till lately quite unique resources of the London Small-pox Hospital should have fallen into the hands of a man so able to appreciate the uses (beyond those of the mere treatment of disease) to which they might be put as our late lamented friend James Furness Marson. His retiring habits kept him much from the world; but he has left behind him work entitling him to the gratitude of all mankind. The task he set himself to perform, in determining the influence on the course of small-pox which vaccination, and different degrees and kinds of vaccination, had on persons who, after having undergone the process, had still the misfortune to contract small-pox, was one which called for qualities which he pre-eminently possessed. The most painstaking accuracy of observation, perfect exactness in recording, a power of weighing facts and not merely counting them, sagacity in deduction, with ingrained habits of caution, were all his; and by the steady application of these qualities to the examination of several thousand cases of small-pox in sixteen years, during which there was scarcely one day without recorded observation, he was able to arrive at conclusions on the subject of his studies which he felt he might safely put forward as unassailable. Another sixteen years' observations of the same kind did but confirm those conclusions. The standard which he thus established must ever be our test when we use the words "successful vaccination". Vague applications of that term (such as, I am sorry to say, I see even now, and not unfrequently) can no longer be tolerated.

The extensive official inquiry into the state of vaccination in England which was made in 1860-64, disclosed the very imperfect way in which, according to this standard, vaccination had been performed; and it disclosed also that, notwithstanding that several years had elapsed since Marson's observations had been given to the medical profession, its adoption was but very slowly finding its way into practice, whether public or private. The arrangements, too, under which public vaccination was performed were not found to be such as were most conducive to its successful performance. Under the Act of 1867, therefore, power was taken to regulate public vaccination with special reference to its quality; and regulations were issued—(1) for reconstituting the arrangements for its performance so as to obviate to the utmost the necessity for the use of dry or otherwise preserved lymph, and to secure its habitual performance from child to child under the best conditions of selection of lymph; (2) for requiring of all public vaccinators such performance of the operation as was necessary to the attainment of the required standard; and (3) for making a part of the payment for public vaccination dependent on the quality of the vaccination done. The effect of these regulations has certainly been to produce a most remarkable change in the efficiency of the vaccination now publicly administered.

The time for testing this vaccination in its influence over small-pox epidemics has not yet come. The vaccinated persons who died from small-pox during the epidemic of 1871, and also those who have died during the recent, or I should rather say the present, metropolitan epidemic, have been almost without exception persons above fifteen years of age, and whose vaccination dates long anterior to the changes of which I have been speaking. It is the past, not the present, vaccination which has been on its trial: the vaccination such as was described in the Reports of the Medical Officers of the Privy Council, 1860-64.

The public vaccinators of England have for some years now been subjected to systematic inspection, and from this we are able to affirm that great improvement to which I have referred as having taken place within the last eight or ten years in the quality of the vaccination so done. The genuineness of the vesicles habitually produced, their sufficient number, their regular course, and their characteristic cicatrices, are attested. It is certain that our defences against small-pox, as dependent on the quality of vaccination, are much in advance of what they were; and, as time goes on, the proportion of the population not merely vaccinated, but thoroughly vaccinated, must be a constantly increasing proportion. Imperfections in individual cases there must sometimes necessarily be. The best vaccinator, operating under the best conditions, may in particular cases fail to produce the full effect he desires; and, when the conditions of working are inferior, when preserved lymph has to be used instead of lymph from the arm (as in rural districts must in many cases be), then cases of comparative failure will, of course, be more common. The assertion is not of the universally, but of the generally, satisfactory result. In estimating, however, the effects of these improvements on the protection of the population at large, we must bear in mind that one-third of the primary vaccination

of England is not public vaccination, and that of this third we can give no account. So far as concerns personal carefulness and a knowledge up to the science of the day, we have no right to suppose that the vaccination of private practitioners would, as a rule, be found behind the public work; but, in regard to the arrangements most conducive to the success of vaccination, private practitioners must necessarily stand at a disadvantage. I am afraid this disadvantage sometimes is very considerable and of serious effect. I will give one illustration. In 1874, there were certified in this metropolis two hundred and fifty-one cases as legally insusceptible of vaccination. They had been vaccinated three times without success; but they remain quite unprotected against small-pox. I will undertake to say that none of these cases had been vaccinated at a public station. There is one further drawback to which I must allude, operating still, I fear, in particular places in some parts of the kingdom, in which a certain class of practitioners make vaccination easy by performing it at a low fee inefficiently—*i. e.*, by one or two punctures only.

These sources of occasional imperfection—wherever they occur—render more urgent the application of that process of further security which I do not think should be omitted even in the most perfectly vaccinated, to the importance of which the profession are becoming more and more alive, and which they are more and more advocating everyday: the process of revaccination—revaccination not practised spasmodically, if I may so say, at times of present alarm, but revaccination practised regularly and systematically on each person as he grows up.

Revaccination of the general population is not in England compulsory, nor do I know that it would be wise to require it; but there are many ways in which it might with great advantage be made so indirectly. In the military and naval services, and also, I believe, in some branches of the civil service, it is an essential condition for employment. It should be made so throughout the whole civil service, and in all factories, workshops, and establishments under any degree of public control. Large employers of labour have great opportunities (the exercise of which, I need not say, entirely voluntary) of assisting in this way; and these it is especially desirable they should use constantly and regularly, though it is usually only in times of panic that they are willing to use them at all. Even for this we must for the present be thankful; but what we want above all things is to get systematic revaccination established—to get it to be looked for as regularly at fifteen or sixteen years of age as the primary vaccination of an infant is at three months. The law provides for every individual a right to a gratuitous primary vaccination, and to a gratuitous revaccination at the public cost; and it is of the utmost importance that the two kinds of vaccination should proceed regularly together, dependent as revaccination must always be on a supply of primary lymph.

In proportion as we shall succeed in getting the foregoing systematic measures adopted (and we are already, as regards most of them, marking distinguished success), so shall we be free from alarms consequent on epidemics of small-pox. I do not say that we shall get rid of epidemics altogether, for an universally protected population I can hardly conceive; but we shall be taking away from them the pabulum necessary to their extensive diffusion.

The laws which determine the intensity of particular epidemics of disease, whether of small-pox, scarlatina, measles, or other diseases of like kind, are to a great extent unknown to us. We know not why towards the end of the seventeenth century (there was no inoculation then to account for it) small-pox should have been so much more fatal than at the earlier part of the century. Inoculation doubtless had its part in causing the small-pox mortality of the latter part of the eighteenth century to be greater than that of the earlier part; but I doubt if that will account for the whole difference. And now, towards the end of the nineteenth century, we witnessed lately an extraordinary and world-wide extension of the disease, exceeding in intensity anything known since vaccination was introduced. Why was this? We know not; the matter is not within our control. *But what is within our control is our defences.* On looking back at the history of that epidemic, to draw what lesson we can from it, we find that where these defences were perfect, according to the rules I have laid down, they stood us in perfect stead. The intensity of the epidemic, the disproportionate number of malignant cases, caused the death-rate, indeed, in proportion to cases, to rise beyond the average in all persons attacked, whether the unvaccinated, the badly vaccinated, or the well vaccinated, but the *relative proportion* was preserved. The deaths among the well vaccinated were very few indeed; and among the successfully revaccinated, as far as we have any opportunity of knowing, scarcely any at all. The serious mortality in that epidemic in the vaccinated, or so-called vaccinated, was the simple result of our vaccination having been left to take care of itself, and, therefore, of our defences not having been in proper working order. So, also, as far as I have been able to learn,

with regard to the vaccinated in the present epidemic in London, which has manifested the same malignant character as that of 1871, but which has been attended, however, with much smaller mortality, doubtless because the prior epidemic had caused so large a number of the susceptible to become secure against future infection, either in having then contracted small pox or obtained revaccination.

The gist of these observations has, you will perceive, been to induce you mainly to rely on a continuance of the system now in progress, with such improvements in administration as may be shown to be necessary, as our best security against future small-pox. The task we have before us is to build up a properly protected population. Epidemics of small-pox may be looked for, and perhaps for some time to come epidemics which may cause some considerable mortality; but severely fatal epidemics should by-and-by be made to cease from amongst us. We are in possession of the means, if we rightly use them; not, perhaps, that we shall ever make such perfect use of them as to leave nothing to be specially done when an epidemic arises; but that special work will be brought within reasonable limits—limits such as will render its performance of easy attainment. Special provision with regard to vaccination, at times when small-pox is epidemic, is, I need not remind you, within the regulations issued under the Acts now in force.

### ANIMAL VACCINATION.\*

By JOHN GREENE, L.R.C.P.Ed., Friday Bridge, Birmingham.

By the courteous invitation of this the Metropolitan Counties Branch of the British Medical Association, I possess the valued privilege of expressing before you in a brief manner my opinions and views upon the subject of animal vaccination. My experience has not been very limited. I commenced the practice shortly after its introduction into this country by Dr. Blanc, and continued it more or less assiduously for eight years, during which time I either inoculated or experimented upon about four hundred animals chiefly with Belgian lymph.

I approach the matter to-night in the character of one having a profound conviction of the value to mankind of the great discovery of Jenner, and with an equally strong conviction that we have not yet reached perfection in its administrative application. I desire that a fierce light should shine on this new movement of animal vaccination that shall make manifest alike its weakness and its strength. Since the passing of the first Vaccination Act, it seems to me that the profession have ceased to exercise that high interest and activity in the matter which characterised the early years of vaccination, and have rested securely cradled in the thought of departmental infallibility; but, at the present time, a new desire has arisen, shared in by the present eminent adviser of Her Majesty's Government, to examine the subject afresh, to mark defect, and find a remedy. It may be hoped that such a spirit may lead to the capitulation of the anti-vaccinators by punishing them with a famine of reasons.

I hold the opinion that, if it can be found possible to improve a little further our present arrangements, we shall be enabled almost wholly to banish small-pox from the land. In the considerations which will here arise, the question of lymph-supply goes at once to the root.

If it be proposed by anyone that animals should be made to afford a large portion of this supply, and that a considerable percentage of the population should be protected by direct inoculation, I would immediately reply in the negative; it would be cumbersome, expensive, and, in fact, impracticable for many reasons. I feel sure this position does not require elucidating in this room; but, as used in a limited manner and for a special purpose, I desire to advocate the supply of lymph from animals. I allude to the advantages the method presents of an ever-flowing fountain of lymph of a relatively high standard of activity for the renewal of stocks at any time, when opinion or accident makes it requisite. Now, passing over for a moment certain important matters involved in this proposition, I think it possible that the detail could be so arranged that, whilst fulfilling the above splendid duty, it would at the same time discourage any wide tendency on the part of the public to have recourse to it in a too frequent or unnecessary manner, which would soon result in the destruction of the chief function warranting its existence. For instance, by limiting the production of cow-pox to one establishment for the whole kingdom, the undesirability of adopting that lymph for general vaccination would be proclaimed of itself; that a few sought and obtained vaccination in this manner would be merely a necessary incident, and careful restrictions might be trusted to prevent any excess in the number without impairing the liberty of those whose minds were set upon it, or

who entertained a fanciful or conscientious objection to hominal lymph. This is a matter of administrative detail not at present in discussion.

To proceed: the question of having occasional recourse to new stocks divides itself into two parts: 1. Whether science tells us as a fact that it is necessary for the preservation of power; 2. Whether, on any other grounds, it is expedient. To answer the first in the negative would not necessarily nullify the latter, whilst to answer it in the affirmative would involve it. To attempt to decide the leading question is to enter upon an endless struggle of argument and statistics out of which can proceed no definite issue which should stand spotless from doubt. Dogma is a poor refuge from this dilemma; the evidence thereon is, like the cow-pox itself, having an effect which is the mean between inoculability and receptivity, and so will perpetually vary with us individually.

It would be an uncongenial task for me to compile or tabulate the various facts I have read, or to quote opinions; all these are public property. I will not weary you with a twice-told tale; for the same reason, I will not again go over the ground taken by myself in the pamphlet I wrote in 1870, on *Good Vaccine Lymph*: still I must make a few remarks upon the point.

It is a fact that a number of authorities, each equally reliable, industrious, and trustworthy, have investigated the subject of lymph-degeneration, and have come to diametrically opposite conclusions. Now, many of these conclusions do not admit of an easy explanation in an adverse sense, or of a matter-of-fact explanation at all; so that we are bound to the logical inference that there are circumstances influencing the history of contagium (be it dead or living) of which we are ignorant—a truism you will say. Yes! But in argument we are apt to forget it, and build a house on sand. We have yet to learn the mysterious agency which decides the advent of an epidemic of small-pox, measles, or scarlet fever, or influences their disappearance or decline. Of the causes of their varying malignancy at different epochs, and eccentricity of incidence, we know little beyond certain subsidiary facts of local hygiene. It is not more certain that the amount of that peculiar material in the human organisation upon which variola thrives differs in individuals at all times than that it does in populations at diverse times, and, as the intensity of the effect of an inoculation of cow-pox must be the means of the exciting power of the contagium and the receptivity, it follows that, during periods when the latter is low, successive and frequent inoculations of the same lymph must result in an average reduction or degradation. Careful selection doubtless will diminish the rate of, but cannot extinguish, the process. This slow alteration may be going on in one district and not in another; or all over the kingdom imperceptibly at one time and not at another. Thus only is it possible to account for conflicting evidence where no other explanation is obvious. Thus will it seem easy to produce a vaccinoïd affection bearing the same hastened relation to fresh Jennerian cow-pox as varioloid affections have to typical variola. Jenner himself has stated that a bad inoculation of variolous matter itself will not protect from variola. How much less, then, must a mere vaccinoïd inoculation! In this way do I account for the large number of persons found badly protected at this late date in the history of the prophylactic.

But, if we remove the vexed question of renewal from the ground of personal conviction to that of balanced evidence, we reach the neutral zone of doubt; and here I venture to think that common sense may and will come to the rescue of perplexed science, and answer the second part of my proposition as to the expediency of renewal in the affirmative, assuming that we have the power to obtain the right article. This expediency is demonstrated by the fact that hundreds of medical men whose opinions have been formed by their own meditations and experience earnestly desire this renewal, and also thousands of the instructed part of the community at large. That there are no means available for doing so, is a plausible ground for complaint in very wide circles. It is not imperative to examine the varied reasons upon which the demand is founded; but it exists, and I affirm it can be met.

We will pass over the history of animal vaccination, from its origin in Naples and importation into France, to its development in Belgium and the United States of America. Suffice it to say that it is known that, with a sufficient capital and assiduous care, a continuous supply of animal vaccine may be afforded. It is in the character of a witness as to the qualities of this virus that I have the honour to be present to-night. In the first place, however marked are the differences between children vaccinated by the same lymph, the differences in calves are greater. Here lies the difficulty of lymph-cultivation upon the animal. It is the most care-compelling pursuit I can think of, requiring, in addition, capital and every material convenience. Looking, then, to the fact that its perfect cultivation is dependent upon human judgment and circumstance, and not upon a natural process, I cannot conceive how the assertion can be justified that cow-pox on calves, being on its own natural soil, can never change. As for the argument of "natural soil",

\* Read before the Metropolitan Counties Branch.

where is this? Is it not acknowledged, in this country at least, that the juices of the cow have converted human variola into something else, different though allied. It is, then, a domesticated alien in the bovine species, and more, not less, liable to degenerate than the same taken back to man, where, though changed, it would be less alien. As a matter of fact, the same gentlemen who proclaim the "natural soil" theory are loud in praise of the calves reducing by repeated inoculation the two active qualities of original cow-pox. They suppose this process to cease at an arbitrary line. This is a dogma of a faith that shall have no martyrs: a sort of limited liability in logic. But, in saying thus much, I desire to apportion the full value to experience and judgment in cultivation. If this be united with favourable climatic and general circumstances, I can understand how years might elapse without any particular change. A case in point is the successful propagation of the Beaujeu cow-pox by Dr. H. A. Martin of Boston, United States. It appears that this stock has been passed through eight hundred and thirty-four animals, and that Dr. Martin cannot find the smallest diminution in its effective qualities. There is no occasion to mistrust the enthusiasm of Dr. Martin. It must be avowed that this gentleman has exhibited a remarkable skill in cultivation and energy in carrying out his object. In his latest "report", published this year, he writes as follows.

"During the six years and nine months since I introduced animal vaccination, I have vaccinated and superintended the vaccination of five hundred and eighty animals, besides some forty more in my earlier experiments. From these animals over eight hundred thousand charged points, and an uncounted but very large number of crusts and tubes of fluid-lymph—many thousands—have been issued. This virus has been consumed by nearly nine thousand physicians, whose names are in my register, besides a very large number whose names are not recorded. I have supplied virus to vaccinate many cities and other municipalities, great and small, to a very large number with quantities of from five hundred to eighty-four thousand points. Many of these have been supplied with aggregates of from five thousand to fifteen thousand points each. I have supplied the Departments of War and of the Interior with large quantities of virus, principally in the form of crusts, for the vaccination of troops, frontiersmen, and Indians, and, in one instance, supplied three thousand points for the arrest of a variolous epidemic which threatened the annihilation of an Icelandic colony in British America."

The figures given here constitute a big thing even for America, and it must be remembered that Dr. Martin is an Englishman born; but, unfortunately, he fails to give even an approximate estimate of the success with which this lymph has been used. Now, I will acknowledge that Dr. Martin may be cleverer than myself, but of this I am sure: that, had I sent out virus in this wholesale way, success would have been very mixed and the result pernicious. In my humble opinion, such a wide attempted application of the method of animal vaccination is an outstepping of its true function in a rash manner; one that is likely to end in mischief and mistrust of the method, perhaps involving with it the real good that is in it. Still, according to Dr. Martin's report, the conditions of success have been much improved of late, but that will not shake the opinion I have given. Be this as it may, Dr. Martin must by this time have discovered the best practical method of procedure to a greater extent, I am inclined to believe, than any one else. Therefore, I wish that Government would send out a commissioner to ascertain from Dr. Martin many points of interest; for, whatever may be the limit which ripened judgment may place upon animal vaccination, if it be ever used in this country officially and only for the purpose of renovation, skill in cultivation would be essential.\*

I have argued just now that degeneration of lymph takes place alike on the calves as on man. I will go further, and state that my own observations on the animals have convinced me that such is the fact. Therefore is it that calf-vaccination is not a *ne plus ultra*, but only a link in the chain of our desires mounting to the fountain-head, that Jennerian modification of the old inoculation, the small pox of the cow: "*variola vaccinae*". The animal is an useful intermediary by which we may multiply the primary virus *ad libitum* and deprive it of the too violent action that Estlin and others found so objectionable.

Before I consider what means we possess of having recourse to this primary virus, I will bear witness as to its qualities when transmitted through the heifer. My experience of stocks of primary lymph has been confined to those in use in Belgium. The Esneaux stock was discovered by M. Petry in August 1868, and substituted at once for the Beaujeu virus, then actually in use on the Belgian calves. This stock I had in constant use for nearly two years in the same manner.

\* Since writing the above, I have seen a series of coloured photographs of vesicles raised by Mr. Ceely from Dr. Martin's lymph. They are admirable, and will bear comparison with those obtained from the Esneaux lymph.

The animals chosen for inoculation were from four to six months old, of no particular breed, colour, or sex, but well conditioned and with clean and blooming skins. They underwent a short preparation, according to the previous circumstances of each animal. A multitude of difficulties arose at first, which were never wholly removed in my case, because I did not desire that the subject should monopolise either my attention or my capital: a condition imperative to full success, whether it be intended to thrust calf-vaccination into what I would call an undue position before the public, or only to its rightful place before the profession; but these difficulties and mistakes of the early days need not recur in future, now that there is a large accumulation of experience in different countries to learn from.

The manner in which the animals are controlled for inoculation, the part in which this is done, and the method, are known. Of the subsequent treatment, little more is needed than a good clean warm stable, the same diet to which the animals have been accustomed in their preparation, that they shall be prevented from licking the part, and have the society of their fellows.

Of the effect of the Esneaux stock upon the calf, I cannot do better than show you these photographs, taken for Dr. Blanc in 1868, and kindly lent to me by Mr. Ceely. These exhibit in perfection the vesicles on the heifer. The lymph of this stock was very ineffective, the smallest merely accidental scratch was sure to "take"; good clear lymph was obtainable on the fifth and sixth days. The vesicles then rapidly matured, and the crusts of such as were left undisturbed fell about the twelfth day.

There is one point of discrepancy in the evidence of others and myself. It has been stated that disease does not cause any suffering or disturbance in the average state of health of the animal. Now, with the Esneaux lymph, which in every way I judge to have been a model stock, a marked alteration on the fourth day was nearly always observable: the animal ceased from food, and became dull in appearance; if it had been restless before, it was now quiet; and if it gave voice at all, it was a very low poorly sound indeed. This condition was, however, only transitory; in a few hours, all was right again.

We next have to consider the effect of this transmitted primary cow-pox upon the human subject; and it is this that I desire most to impress in view of the course of the affection which we are accustomed to see, from long humanised lymph whose pedigree has been uncrossed, or indeed, if it be possible, with lymph of the Esneaux source itself, at this date. Concerning these differences, I may mention that, when quite a young practitioner in 1859, I had scarcely a single idea of the literature of vaccination; yet, by reading a stray copy of Jenner's *Instructions*, which had descended to me, I had become dissatisfied with the lymph then in use. I ignorantly tried to improve it by vaccinating two storks with human lymph, which appropriately failed. I only mention this to show the impression made upon me by Jenner's description, and to suggest how pleased I was when I first saw the effect of the Esneaux lymph in 1869. In all my experience, I had never seen anything like it. The vesicles developed very slowly; on the eighth day, in the larger number of cases, there was not even a commencing areola; they were very firm and clean-looking, standing vigorously up from the skin. The areola came on the tenth day, sometimes on the ninth. The vesicles continued to increase until the twelfth day, sometimes attaining a development nearly equal in size to a three-penny-piece, always finer than those got from the old lymph for the same scale of insertion. The crusts were hard and black, and fell about the twentieth or twenty-second day. A common remark made by mothers on the eighth day was: "Why, doctor, this is a poor effect to what it was in the other children." This desire for brilliancy was fully gratified in a day or two. Now, this course tallies exactly with the descriptions of Jenner, Willan, and others; and I do not think it possible for any person in this country to produce, at the present time, a stock that shall equal it, on an average result, in the above particulars.

There are yet more important differences to mention: those of constitutional action. These were decidedly more marked than with the old lymph; not a single child escaped entirely; all were made manifestly poorly, restless, and feverish—sometimes so markedly that the parent has afterwards stated that she thought she would have had to send for me.

The secondary dermoid affections, of which I had had little or no experience with the old vaccinations, were now brought under my notice quite frequently: vaccine lichen coming on about the fourteenth day (I think this must be the secondary eruption delineated by Willan), a rash like measles, and also the fac simile of one I have noticed in small-pox just before the eruptive stage.

I made acquaintance now, for the first time, with genuine eruptive supernumerary vesicles. This happened five or six times during my use of the Esneaux lymph, and on each occasion only *one*; several of

them occupied places where it was impossible they should have been accidental inoculations; once in a most unusual position, the very top of the head in a child with little hair. Since the Esneaux stock was lost, I have never seen a supernumerary vesicle, while the chances of accidental inoculation have remained the same.

A great deal has been said about the uncertainty of animal lymph. I acknowledge there is some truth in this allegation: but I never found this very troublesome. Care goes a long way to rectify it. I believe that this objection would be of no consequence with a good stock, with skill and judgment in cultivation, and with the limitations of the method I have already advocated. I found that, with the lymph from some animals and the avoidance of hurry in its transference, it was equally as certain as human lymph. That this obtains with some calves, seems to carry the inference that it is a matter of judgment in selection. Of course, in any case, I assume that only the finest vesicles are used.

In revaccination, my success was good; by counting in every mere approach to a vesicle, it exceeded the percentage obtained in Belgium, namely, 63.2; but these of mine were always done direct. Two or three times, I saw troublesome ulcerations follow on each occasion in pale-looking patients, who fainted from the operation. In all cases that succeeded, the febrile symptoms were well marked; in many, rather severely; in several, so much so as to confine them to bed, the measly rash appearing and the axillary glands being much swollen. With these few exceptions, I was quite satisfied with the use of this virus for revaccination.

Through all my experience of animal vaccination in primary cases, I have not once had cause for regret: at first, several gentlemen to whom I supplied it, and who used it with the same amount of insertion to which they had been accustomed with old lymph, were rather alarmed with its severity, and no wonder. In this connection, I should like to refer to a letter of Mr. John Pearson, Surgeon to the Lock Hospital, published in the appendix to Willan's *Vaccine Inoculation*, 1805. He says: "When the inoculator makes several parallel and transverse incisions in the same place, the inoculated part inflames violently at the period of efflorescence, and the inflammation often extends from the shoulder to the elbow. The child becomes extremely ill, large erythematous appearances take place on the arm, forearm, the neck, the side, and even on the lower extremity; a fortnight or three weeks will sometimes elapse before the child can be considered free from all danger." He further somewhat superfluously characterises this as an improper vaccination. I have seen this precisely as Mr. Pearson describes from using the new lymph like the old. What is more common now-a-days than this method of insertion which he condemns? The virus of the first human remove from the calf, singularly enough, produces more intense local effect than that from the animal, but this is lost in the subsequent removes. On one occasion, a very remarkable thing happened in the practice of a neighbouring surgeon, to whom I had supplied some of this Esneaux stock. He vaccinated a clergyman's child, six or seven months old, with lymph from the first human remove; the vaccineifer was healthy. I was desired to see the case on the twelfth day, and found a very much inflamed and swollen arm, with a series of from twenty to thirty full sized vesicles exactly like small-pox, grouped irregularly upon the upper arm, lying thickest about the seat of insertion. No other vesicles appeared on any other part, and the case did well ultimately.

Of the lymph-stock of Vauves, which in 1870 superseded that of Esneaux, I have little to say. It was at first pretty much the same as the latter, but after a time it ceased to possess those active qualities that have here drawn my praise. I became dissatisfied with it: it no longer had the brilliancy and power of the Esneaux lymph, nor its infective qualities. The particular advantages to which I have referred, as manifested by the former alike on the calf as on the human subject, were categorically absent in degree. I was of opinion that it no longer accomplished the great *raison d'être* of animal vaccination—namely, the supply of a lymph of as high a standard relatively to variola as judiciousness and safety would permit. The grounds for my dissatisfaction I found to exist alike, whether I cultivated the virus from calf to calf, as I had hitherto successfully done, or inoculated the animals each time with a fresh supply from Belgium. I therefore, about fourteen months ago, discontinued to reproduce the lymph on my own calves; but I have always held that the advantage which calf-vaccination gives to overcome the strong dread in some people of the transmission of diathetic diseases by human lymph, was worthy of attention in a subsidiary or collateral way. For this reason, I still continued to procure and use Belgian lymph when it was requested, and because, although it would not bear comparison with the Esneaux virus, it did give a fair result, equalling good human stocks, minus, however, their certainty. The present lymph in use in Belgium has been derived from Milan. My knowledge of it is limited to its action

on the human subject, and from tubes alone. It would be unfair, therefore, to base any strict comparison upon this, but I am fully able to state that I am satisfied with the course and appearance of the vesicles raised from it, and with the signs of constitutional action; but, no matter how good the present stock may be, it does not affect the argument of my paper, nor is it possible that this should be neutralised by any matter-of-fact explanation.

Now, having arrived at this point, let me, in the briefest possible way, consider what is the prospect of finding a remedy for this precarious nature of the virus. I appeal to the Government to institute systematic efforts to discover fresh cases of cow-pox, and, when found, to take the lymph and experiment for themselves. Are they not morally bound to seek the truth by investigations that shall take cognisance of all well-advanced assertion; and, if it should be found that animal vaccination is either pernicious *per se*, or likely to become so by mismanagement to a greater degree than by mismanagement of merely human vaccination, which I affirm is true, then, is it not imperative that the practice of the new method in private hands should be forbidden by enactment? On the contrary, if it be found advantageous, must they not adopt it, to some extent, as one of their resources, on the same principle as that on which the Vaccination Act itself stands?

It is with very great pleasure that I hear the authorities have determined to repeat the experiments of that distinguished member of the Association, Mr. Robert Ceely, upon the artificial production of cow-pox, for it is this that should form the real basis of effort in the direction of new lymph-supply. Naturally, a fresh case of cow-pox could not always be forthcoming just when it was wanted.

I am one of the few who have been successful in producing artificial cow-pox; and, though I have tried many times, have not again succeeded. It is tempting to enter upon this question fully, but time will not allow. I hear that the first set of experiments conducted by the authorities have failed: no doubt, they will try again till they do succeed. I should look hopefully to increased experience to remove the difficulties attending this operation. Were I again engaged in this attempt, I should select new milch-cows with their first or second calf, in the very highest condition of health possible, with their skins full of the juices of the rich summer grass. I should select amongst the number several white cows and Alderneys. I would do the inoculation by deep incision with varicellous lymph of not too late a stage, and from a sample mixed from several cases. I should use it with and without glycerine; the air of the stables I would have rather warm and very moist. I think premature desiccation is one of the difficulties.

In the case in which I was successful, I did not wait till the vesicle had quite formed, but took matter from the most prominent of the tubercles, passed it consecutively through two calves, and then on to two children, obtaining in one of them two magnificent cow-pox vesicles, and nothing more.

Gentlemen, we are in the presence of a crisis in the history of vaccination. Nations, dissatisfied with the spread of small-pox, yet still trusting in the kindly prophylactic, turn their eyes towards the new manner of direct inoculation. Now, more than ever, must our noble profession guide our country wisely. This favoured land, that first received the fairy gift through the wisdom of Jenner, must not lose it through the folly of his successors. We must refuse to adopt this Neapolitan practice to the extent advocated: it is cumbersome, precarious, and far more liable to mismanagement than is our present system. Let us rather take a lesson from the practical botanist, who, shaking fresh pollen into his old bloom, produces a more vigorous specimen. Let us find means, through the calf, to renew our old stocks at will from the "variole vaccine". That lymph which gives the greatest constitutional affection of the right kind for the smallest number of insertions will give the greatest local beauty, and well-nigh absolute security from variola.

## ERYSIPELAS AND VACCINATION.\*

By SAMUEL LODGE, M.R.C.S., Bowling, Bradford.

It is with some diffidence that one approaches the subject of erysipelas here, in this hospital and in the presence of such a number of distinguished practitioners: nevertheless it may be that the disease, considered as a result of septicæmia in connection with vaccination, and treated by what I have always designated the Leeds method, could not be more appropriately discussed by any society than by the West Riding Medico-Chirurgical. Mentioning to my friend Mr. F. Hall

\* Read before the West Riding Medico-Chirurgical Society.

last year—who had spoken to me of one or two cases of erysipelas following vaccination in Leeds—that I always used the tincture of perchloride of iron. I think he replied that *it had been tried* in the cases alluded to without effect. At the first glance, this answer looked discouraging enough; but I question if further observation and experiment do not enable us, as vaccinators, to look upon the disorder with confidence and serenity, rather than with apprehension and dread. I have seen two cases of fatal erysipelas in children, and the treatment by iron was resorted to in both. I make no difficulty in admitting that, whatever had been done for those unfortunate creatures by way of remedies taken or used, the result would have been the same. The cellular parts of the bodies seemed disorganised precisely as we have all observed them in deep burns—the connecting tissues rotted away; but in neither of these cases was anything suspected as traceable to vaccination. They were purely idiopathic; they occurred at different periods, in different places, and did not appear at all contagious.

It is now proper to notice one particular direction of the vaccination authorities. We are “not to use virus from vesicles surrounded by inflamed areolæ”. Why? Because the inflammation may be erysipelas, probably. There seems to be some mistake here. Observation has taught me that the inflamed areola, as ordinarily seen, is not erysipelas; and that, if it be only brushed over with a weak solution of iron, it will certainly subside without further trouble. Of course, it is not to be inferred that the red ring now spoken of will end in erysipelas if let alone. On the contrary, the contention is, that this distinguishing mark of keen virus and active circulation will, in most cases, return to the natural condition as the vaccine disorder exhausts itself. But, to make the matter perfectly safe, it is only necessary, after puncturing the vesicles, to treat the inflammation in the manner above described. A step further takes us into a more doubtful and dangerous region. If, after vaccination, beyond the inflamed surface—say near the elbow-joint, but divided from the vesicular inflammation by a circular line of raised hard pale skin—there should appear a patch of dull red colour, that is quite another matter, and I should not recommend that lymph from such an arm should be used.

The erysipelatous circles or spots, or whatever shaped discoloration the skin may assume, must be treated with the iron at once; and wherever the diseased patches may extend, to them must its application be continued.

I have seen erysipelas as the result of vaccination in three cases, and in one of them almost every part was attacked and painted over. The three cases referred to occurred in our own practice about four years ago. There was nothing uncommon about the appearance of the vesicles; in two of them, the cow-pox inflammation was but slight. I did not see the third until afterwards. Finally, they all recovered. From that time, I have always applied the tincture of perchloride of iron to any suspicious-looking arm; and since having found every painted case to do well, I now use it in all without distinction. In fact, mothers and nurses would not contentedly take their charges away if the treatment were omitted.

Mention has already been made of one particular direction by the vaccination authorities to public vaccinators, and we now proceed with due humility to remark upon another.

It is somewhat unquestionable how far the Hunterian dogma is correct, that two disorders having similar characteristics cannot exist at the same time in one person; but it is difficult to divest one's mind of long-conceived impressions, and perhaps the following case may be interesting to some practitioners who, like myself, do not entertain the belief of all that is old being false and all that is new true. Small-pox was raging in a part of our district, and we were engaged in revaccinating the people. The grown-up daughter of a man who was lying ill of the disease came to be vaccinated. She had not been vaccinated in early life. I made the usual light scarifications, scarcely drawing blood, when the woman, without any apparent suffering, suddenly fell down in a swoon. It was thought that a fine strong young woman should not faint from so slight a cause; and, when she recovered, such answers were obtained as convinced us of her having been ill before coming to the station. This actually proved to be the case, for in a few days a regular crop of small-pox pustules appeared. The disorder ran through its stages, and the woman recovered well. I need hardly say that I anxiously watched for the advent of the cow-pox; but it never came.

It is possible that two analogous diseases may exist in the same person at the same time; but it does not seem easy to believe it. Then what are we to think of this direction to public vaccinators: “You are to be careful not to convey the blood of the patient you are operating upon back to the vesicle of the child from whose arm you are taking the lymph”? Water, a cloth, etc., are always to be used—and by me always are used—to purify the lancet after every time it touches the

new patient, in order that the blood of a child suffering from cow-pox at its greatest height may not be contaminated. Now, bearing in mind that the surface to which the lancet is applied for lymph is not an absorbing, but a rapidly exuding one, I venture to suggest that the government theory is physiologically incorrect. Right or wrong, however, this direction cannot do harm; and at any rate it necessitates caution.

My friend Mr. Parkinson of Bradford assures me that he now vaccinates with the same lancet that he has used for thirty years, and that he has never met with a case of disease consequent upon vaccination performed by himself or anybody else. Dr. Foster of Leeds, who has been a vaccinator over forty years, declares that he, in all his experience, has never seen a bad result from vaccination, nor even any approach to such a thing.

I have sometimes operated, according to the instructions of Dr. Stephens, by a number of small scarifications; at other times, by the tattoo dots of Dr. Willshire; and very often by the long line of the oldest practitioners; and, I am bound to say, with a like good result in all, so far as the prevention of small-pox has been concerned. In short, I may say that I have never known that terrible disorder occur to a patient that I have effectively vaccinated.

Fearing that I may be misunderstood, let me add that I have treated small-pox through three epidemics; that I have known pregnant women to suffer from it, the lives of both themselves and their offspring being sacrificed; and, finally, that I have attended one patient who died of a second confluent attack.

## ABSTRACT OF A PAPER ON VACCINATION AND REVACCINATION.\*

By F. P. ATKINSON, M.D., Kingston-on-Thames.

DR. ATKINSON said it was now generally acknowledged—

1. That vaccination lessens the chances of taking small-pox, though it does not render the reception of it in after-years altogether impossible.

2. That vaccination, in most cases, greatly modifies the character of the eruption and lessens the severity of the attack.

3. That revaccination gives an almost absolute immunity from small-pox, provided it is efficiently performed after fifteen years of age.

The following evidence was then produced in proof of the correctness of the views held.

In the Punjab, with a population of 18,000,000, the deaths from small-pox, according to the statement of Dr. A. C. C. De Renzy, sanitary commissioner in the province, are never less than 20,000 a year. In 1869, they numbered 53,195. In England, the average annual mortality does not exceed five thousand, though, previously to the introduction of vaccination, it was quite as high as in the Punjab. Dr. Brett, Medical Officer of the Watford Rural Sanitary Authority, states that, in 1877, small-pox visited a family, nine in number, residing at Bushey; three had been vaccinated, six had not. All the six unvaccinated persons took the disease, and four died; while the three that had been vaccinated escaped altogether, one of the three being a child at the breast, fed by its mother within two hours of her death.

Dr. Schwarzgruber of Harland, in the *Medicinisches Chirurgisches Centralblatt*, 1877, shows the marked efficacy of vaccination in the epidemic of small-pox which appeared in August of that year. The first patient was a girl aged 5, who had not been vaccinated. She had the disease in a severe form, and, after ten days' illness, died. In the same house was another family with four children; two vaccinated and two unvaccinated. The two unvaccinated—a girl aged 13 and a boy aged 2½—took the disease and died; the two vaccinated children escaped. A third family was visited by the disease; in it also were four children—two vaccinated and two unvaccinated. The two latter had small-pox, and one died; while the two vaccinated escaped, though constantly exposed to the infection. In a fourth family, an unvaccinated girl aged 9 had a dangerously severe attack of small-pox, but escaped with the loss of an eye. A vaccinated boy aged 4, in the same family, had the disease in a very mild form. In a fifth family of eight children, of whom seven were vaccinated, six of the vaccinated had mild attacks of small-pox (four not being confined to bed); while, in the unvaccinated child, the disease proved fatal.

The course of events in other families was similar. In all, there were thirty cases of small-pox among vaccinated persons, with only one death, which may be attributed to the patient having gone, while scantily clothed, from a warm room into the cold air. Of the non-

\* Read before the Thames Valley Branch.

vaccinated (the only ones in the place), eight had small-pox; of these, seven died and one recovered with the loss of an eye.

That efficient revaccination gives an almost absolute immunity from small-pox was shown by the following evidence. Drs. Meigs and Pepper say that, in the terrible American epidemic of 1871-72, they did not see so much as a case of varioloid after successful revaccination even in those exposed. Dr. Welch, of the Philadelphia Municipal Small-Pox Hospital, states that not one of those connected with the hospital who have been revaccinated has taken the small-pox; while three or four of the nurses, who had previously had the small-pox, took the disease a second time. Again, from the report of Dr. William Gayton, Medical Superintendent of the Metropolitan Asylum Small-Pox Hospital, it would appear that only one of the large number (three hundred and sixty-seven) of nurses and others who have been employed at this establishment since its opening (nearly seven years ago) has contracted small-pox, and in this case revaccination had been omitted.

Dr. Atkinson next took up the question whether syphilis could be conveyed by vaccination, and said it would appear, from the cases brought forward by Mr. Hutchinson, that a syphilitic lancet, or blood taken up with lymph from a syphilitic infant, might be the means of transmitting it; though it must be admitted that the experiments of Cullerier and others with mixtures of syphilitic matter and vaccine, and vaccine taken from persons suffering from constitutional syphilis, are most powerful arguments against the idea; and it must also be remembered that, in 1857, Mr. Simon addressed a series of questions upon this very subject to a large number of medical men both in this and other countries, and received answers from no less than five hundred and thirty-nine, with scarcely an exception, entirely in the negative. They declared that syphilis could not be conveyed by means of true vaccination; while, at the same time, they pointed out that, by gross carelessness, it might be inoculated instead of vaccine. One thing is certain: two poisons cannot be present in a true Jennerian vesicle; for lymph may be taken from a vesicle developed in a person who has been vaccinated too late to prevent small-pox and used without the slightest hesitation for vaccinating another child. He next referred to the experiments of M. Taupin of the Children's Hospital, Paris. This gentleman vaccinated a large number of children with virus taken from subjects affected with scabies, scarlatina, rubella, varicella, varioloid, variola, rachitis, scrofula, tuberculosis, chronic eruptions of the scalp, darts, etc., without communicating to the patient any of these affections, either those of acknowledged contagious or non-contagious nature.

When skin-eruptions follow vaccination, the fault is by no means necessarily with the lymph, but often with the constitution of the child vaccinated. If it cannot bear the slight disturbance of vaccination with impunity, it is clear how utterly unfitted it would be to bear the serious disturbance of small-pox, which is the almost certain alternative. It has been asserted, he said, by some that vaccine loses its effect by constant transmission; but, if this be correct, then, for the same reason, the poison of fever ought to become less virulent and infectious each succeeding year; but this is not the case, and though, owing to altered atmospheric influence, prevailing epidemics may for a time die out, they soon return when the conditions are again favourable, with all their former activity. Besides, Jenner, after careful observation for upwards of twenty years, came to the conclusion that the vaccine underwent no change whatever; and, in addition to this, Marson, Ceely, and others of great experience, have proved, so far as is possible, that vaccine matter does not lose any of its prophylactic power by continued transit through successive subjects.

After this, Dr. Atkinson gave the evidence of some of those who have experimented with lymph taken directly from the heifer. During the siege of Paris, Dr. Quinquand had all successful cases with the human lymph, but only a third with heifers'. Dr. Thevenot, with calf-vaccine, had only two successful cases out of twenty-one. Of thirty-two surgeons in Paris who sent in their reports, one said that vaccine from the calf became better after passing through the systems of three or four different children, though bad and difficult to introduce for the first time. The rest (thirty-one) agreed that vaccination from the calf was provokingly unsuccessful, succeeding at the very utmost in only a fourth of the children vaccinated directly, and much less from calf virus tubes or glasses. Of sixteen others who tried the calf-virus, thirteen failed completely. Dr. Gaillard, who succeeded one hundred and seventy times out of two hundred and eighty-three with calf-vaccine, was successful two thousand seven hundred and forty times out of two thousand eight hundred and fifty-six with Jennerian vaccine. After various remarks upon other points, Dr. Atkinson concluded his paper by suggesting that the public should have as much information given them upon the subject as possible, and that every medical man should be particularly careful in the performance of the operation, since it was

clear that small-pox was capable of being banished from our shores, and it was only by these means that the looked-for result could be accomplished.

## EXCISION OF THE RIGHT WRIST-JOINT FOR CARIES.

By J. H. PORTER, L.R.C.S.I., Surgeon-Major,  
Assistant-Professor of Military Surgery, Army Medical School, Netley.

THE utility of excision of the wrist-joint for disease not being altogether accepted by some of the most distinguished surgeons, it may be of importance placing on record the result of one's experience, however limited. The following case I am disposed to consider of interest, as showing that, notwithstanding many adverse circumstances, the operation may be followed by most satisfactory results. In this case, there was well-marked strumous diathesis, extensive scrofulous bone-disease of the joint and soft parts at the back of the hand. The hand and fingers were almost powerless before the operation. There was free exposure of the flexor tendons during the operation. Hemorrhage occurred twice after the operation, necessitating opening of wounds; and during subsequent treatment, the cicatrices reopened and formed into unhealthy ulcers.

J. H., 12th Brigade Royal Artillery, aged 21, had no hereditary history of scrofula, though he presented all the characteristic features of such a diathesis. He had suffered from primary venereal disease, but not from secondaries. He served two years and a half at Malta; and, while stationed there in September 1876, experienced dull aching pain in the right wrist-joint, attributable, he states, to a jar received while endeavouring to move a gun shears. The joint became much swollen; and in November, an abscess formed, which was opened and discharged a small quantity of pus. Notwithstanding free incisions and the introduction of setons, the joint itself became seriously implicated, his appetite failed him, he lost flesh, felt generally unwell, other abscesses formed in the joint, and he was invalided to Netley, where he arrived on May 27th, 1877, having somewhat improved during the voyage. His state on arrival was as follows.

There was a large ulcer on the left arm above the elbow connected with a sinus, at least six inches in length, extending up the arm; and a second ulcer over the elbow, both discharging freely. The right wrist was much swollen; the fingers and thumbs were extended, and with the exception of the forefinger and thumb, which had very slight power, he had no power of flexion or extension, the tendons being apparently adherent to their sheaths; the wrist-joint was fixed, and he had no power of either pronation or supination. Several openings of sinuses existed, one being over and in connection with the fifth metacarpal bone, another on the opposite side of the hand, and three in front of the wrist, all in connection with diseased bone.

Measures were at once adopted to recruit his health. The sinuses in the left arm were laid open, and the wounds treated with salicylic acid lotion. The wrist was treated by free incisions, rest, and the use of the warm arm-bath twice a day, from which he derived great ease and comfort.

Towards the end of October, the ulcers on the left arm had completely healed, he had increased in weight, his health had improved, but the wrist being hopelessly diseased, I decided to excise the joint, and accordingly, on October 31st, performed that operation by Mr. Lister's method, the patient being under the influence of ether, and the limb rendered bloodless. The fingers and thumb were forcibly flexed, and adhesions were broken down immediately before the operation was commenced. There was considerable difficulty experienced during the operation in removing the carpal bones, which were so extensively diseased and softened that it was found necessary to dissect them out one by one, the slightest pressure or force causing them to break down. The radial artery, being much enlarged, required care to avoid it in making the radial incision, and to keep it out of the way and protect it when extirpating the trapezium. The pisiform bone, being much enlarged and diseased, was entirely removed. One small vessel near the bed of the pisiform bone was secured, and the wound was washed with a solution of chloride of zinc, thirty grains to the ounce of glycerine. The large cavity whence the carpal bones were removed was filled up with strips of lint, and Mr. Lister's splint was applied in the usual manner. Hemorrhage occurred in the form of oozing, in about two hours after the operation, and again on the morning of November 2nd; necessitating, on both occasions, the opening of the wounds and application of compresses and perchloride of iron. No vessels could be detected as a source of the bleeding. The wrist and hand now looked in anything but a promising condition, being much swollen,

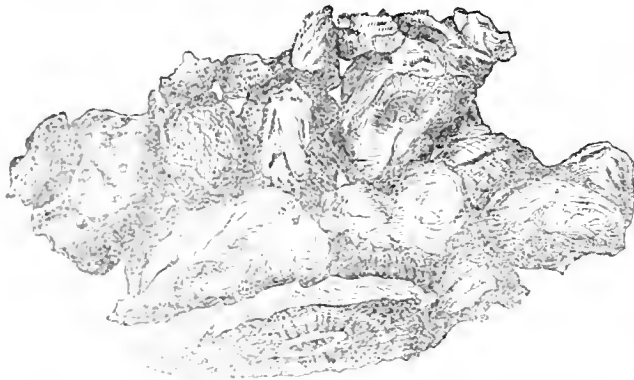

black, and very offensive; matters, however, progressed most satisfactorily, the compresses came away in the copious discharge, which was absorbed and deodorised by the application of sawdust pads.

By November 13th, he was able to be up and about, but was much annoyed by a painful ulcer over the internal condyle, which soon healed when a hole was cut in the splint opposite to it so as to relieve the pressure.

On December 5th, Mr. Lister's splint was replaced by a light gutta-percha splint, moulded to the lower end of the forearm and hand, which gave more freedom of action for his fingers, which had been fixed since date of operation. He commenced using a weight suspended over a pulley on December 11th; which exercise greatly improved the condition of the muscles of the forearm and the power of slightly flexing, extending, pronating, and supinating the wrist.

On December 14th, he commenced writing exercises with a large handled pen, which he has continued daily, and now says he can write a better hand than before the operation.

By the end of January 1878, the wounds had almost healed, when from some unaccountable cause, the cicatrices took an unhealthy action and reopened into most indolent and irritable ulcers, with diffuse swelling and induration of the fingers, hand, and forearm. By change to another ward, alteration of diet, aperient medicine, and warm applications, the parts again took a healthy action, and with the exception of small superficial abscesses forming on the fingers or near the seat of operation, he has progressed most satisfactorily, and is now (June 1st, seven months since date of operation), in the following condition. The wounds of the operation are healed; the wrist has become consolidated; and he is able to brush his hair, sweep the floor, lift a "Windsor chair", and carry a box of coal of 38 lbs. weight. There is fair power of grasping with the hand, which he can slightly pronate and supinate. He is able to flex and extend the thumb, fore and middle fingers, but the power over the ring and little fingers is impaired. He can write with an ordinary pen, pick up a pin, or use a needle in sewing. He has quite given up wearing a splint or sling, and altogether has an useful hand, which no doubt will further improve, should his circumstances in life admit of his maintaining his health at a proper standard.

The illustration represents the bones of the right wrist (natural size), including the articulating ends of the radius and ulna, with portions of the metacarpal bones, kindly drawn by Surgeon P. G. Radstock Young, A.M.D.

## ABDOMINAL TUMOURS AND THE MICROPHONE.

By CLEMENT DUKES, M.D., B.S.Lond., M.R.C.P.,  
Physician to Rugby School and Rugby Cottage Hospital.

THE following negative evidence of the use of the microphone in the isolation of pregnancy, when we have an unknown abdominal tumour, may be of interest to some members of the profession.

Mrs. L., aged 38, residing in Rugby, called on me on June 11th, 1878, saying that she was afraid she had a tumour in her abdomen. She had had one child ten years ago, which died, and she was so extremely anxious to have another child, that I rather suspected to find a phantom tumour. I arranged to see her next day in bed; and, on examination, immediately heard the placental murmur, and presently the foetal heart. Thinking that I should only have a phantom tumour, it had occurred to me whether the microphone could give me any assistance in diagnosis; having, however, found all I needed with my stethoscope, I was not to be deterred from trying to see if the microphone

could aid me still further, and so be of use in the diagnosis of doubtful tumour cases.

Accordingly, on the evening of June 17th, 1878, my friend Mr. G. M. Seabroke accompanied me to my patient with his microphone, which we applied, with this result.

1. We heard distinctly the placental murmur.

2. We could not hear the foetal heart, owing to the movement of the abdomen in respiration making too much sound in the microphone; and, even when the breath was held, it was still disguised, I believe, by the muscular contractions necessary to fix the abdominal walls.

3. On applying the microphone over the heart and to the radial artery, we heard them distinctly.

To-day Mr. Seabroke very kindly made an exquisitely sensitive modification of the microphone, which resembled the end of the stethoscope, and could be placed in any position, horizontally or vertically, and which could, therefore, be much more easily manipulated and applied accurately to the abdomen; still, we were unable to hear the foetal heart owing to the sounds caused by respiration, though it could be well heard with the stethoscope.

## THERAPEUTIC MEMORANDA.

### ALCOHOL AS FOOD.

HAVING read with interest the correspondence upon the above subject, I beg to quote a case that has lately occurred in my practice, which, in my opinion, proves that alcohol is a food. On March 1st, 1878, I was called to see a gentleman, a distinguished officer, who had seen much active service, and found him in a very weak and low state. I was assured by his friends that the only food he had taken, for nearly a year, had been one egg *per diem*, beaten up with sherry. I was sent for in consequence of his refusal to take the egg any longer, or any food, with the exception of alcohol. I persuaded him to take milk, which he did, but only half a pint a day, for three weeks; after which time until the day of his death, on June 2nd, he took nothing but alcohol in various forms. He was nursed throughout by a skilled nurse, in whom I have every confidence.

R. FEATHERSTONE PHIBBS, L.R.C.P.Ed.,  
St. John's Wood, N.W.

## SURGICAL MEMORANDA.

### AVULSION OF A MUSCLE OF THE EYEBALL.

A VERY unusual case of accident came under my notice some timesince in practice, and, as I have never seen or read of a similar one, perhaps it may be worthy of record. The case was one of injury to the eye, and happened as follows. One of the rests for supporting the globe of an ordinary gas-bracket entered the orbit of my patient, a young girl, pierced through the conjunctiva, and, being hooked or bent at the extremity, was entangled in one of the muscles at the external surface of the eyeball. This it tore from its attachment to the bone, and the belly of the muscle lay down the cheek when the girl came to me; the insertion of the muscle into the globe remaining intact. Of course, nothing could be done but cut the muscle as close to its insertion as possible; this was done, rest to the eye was enjoined, and evaporating lotions were applied to the orbit.

The muscle torn away must have been either the inferior oblique or the external rectus, as both are attached close together, at the outer aspect of the eyeball and near the cornea. From the structure of the muscle at its extremity, I should infer that it was the inferior oblique, as its origin was tendinous and by a single head, an arrangement very different from that obtaining in the case of the external rectus, which arises by muscular fibres and is biventral. As the patient did not return, nothing could be gathered as to which muscle it was, from the loss of motion and strabismus which would inevitably result as a consequence of the destruction of the muscle. It may be assumed that no serious inflammatory action or loss of function resulted in the eye as a consequence of the injury; and this is rather surprising, as the force exerted must have been very considerable, and one would have expected that very serious consequences would have ensued to the delicate tissues of the eye. The very serious and unique character of the accident, and the minimum result of injury to the eyeball, have induced me to record this brief note of the case.

J. WILSON HAMILL, M.D., Higher Broughton, Manchester.

## REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE  
HOSPITALS AND ASYLUMS OF GREAT  
BRITAIN AND IRELAND.

## UNIVERSITY COLLEGE HOSPITAL.

COMPOUND FRACTURE OF LEFT ILIUM: PARENCHYMATOUS SUP-  
PURATION OF BOTH PAROTID GLANDS: DEATH.

(Under the care of Mr. BERKELEY HILL.)

FOR report of the following case we are indebted to Mr. A. J. PEPPER, Surgical Registrar.

J. S., aged 56, was working near a railroad and had occasion to cross the line, when a passing train struck him. Immediately afterwards, he was conveyed to the hospital (March 26th, 1878).

On admission, near the left anterior superior iliac spine was a small wound appearing punctured. A probe passed from it downwards and backwards outside the crest for three inches, and struck exposed bone in its course, though whether this was fractured was not ascertained. There was no sign of injury to the thoracic or abdominal viscera; no hæmaturia. There was ecchymosis of the left eye and cheek, but no fracture of cranial or facial bones, and no paralysis.

Two days after the accident, the temperature was 103.2 deg. Fahr., and he complained of severe pain at the seat of injury. The tongue was dry; the teeth covered with sordes. There was acute inflammation around the wound. On the next day (March 29th), the patient's condition was very bad. He had general symptoms of the typhoid state. A counter-incision was made where passage of the probe was arrested over the ilium, and a drainage-tube was introduced. The inflammatory swelling extended for eight inches down the thigh and buttock, and also over the groin. His bowels were open. There was no evidence of peritonitis. Hot fomentations and belladonna were applied to the injured part since his admission, and a stimulating and supporting plan of treatment adopted.

April 2nd. Extensive sloughing had taken place at the seat of injury and over the lower part of the abdominal wall, and extending beyond this was a wide-spread erythematous blush. He had twitchings of the whole body, low delirium, and a vacant fatuous expression. Temperature 100. Bronchitic rales were heard over the front of the chest.

April 4th. Some improvement was observed in his general state; the wound was healthier. Temperature 99.2; pulse 112; respirations 32.

April 9th. The extensive wound caused by the sloughing looked clean, but the skin around was still congested. Over the region of the left parotid, and at the contiguous upper part of the neck, was a puffy swelling gradually subsiding to the level of the healthy parts. There was no fluctuation, but diffuse redness over and around it. Bronchitis was more marked. Temperature at 7 P.M., 102 deg. Fahr. Mr. Hill made an exploratory incision into the swelling, but no pus could be found. The wound was dressed with carbolic oil.

April 11th. The right side of the neck and face presented the same appearance as the left, which was much in the same condition as on the 9th. The abdominal wound was clean. Mean temperature 101.6.

April 13th. Mr. Hill removed a small piece of detached bone from near the iliac crest.

April 15th. The patient gradually became more exhausted, and had constant low muttering delirium till his death at 6 P.M. The swellings connected with the parotids and the abdominal wound had remained very much as described on the 11th.

POST MORTEM EXAMINATION, forty-eight hours after death.—There was no fracture of cranial bones. The membranes of the brain were healthy. The brain weighed thirty-six ounces, and showed no sign of laceration or hæmorrhage. The basilar artery was atheromatous. With the exception of slight submucous capillary extravasation of the lower part of the ileum, the intestines presented nothing abnormal. There was no peritonitis. The liver was fatty and somewhat softened; it contained a few small biliary calculi in the ducts, imbedded in the liver-substance near the surface. The weight of the organ was forty-nine ounces. The spleen was small and soft. The kidneys showed fibroid substitution; each weighed three ounces. The lungs were emphysematous. There was commencing hepatisation of the base of the left lung. All the cavities of the heart were filled with soft clot. The muscular substance was fatty. The whole of the acinose element of the parotid glands was in an advanced state of sup-

uration, the softened and purulent foci mapping out the glandular arrangement perfectly. The interacinose tissue was semigelatinous; the boundary line between this and the secreting structure was marked by a bright red zone of hyperæmia. The tissue outside the capsule of the glands was œdematous. There was no thrombosis of the jugular veins nor of their tributaries. Portions of the crest of the left iliac bone, torn away, were still adherent to the gluteus maximus and medius. A fracture running from the centre of the crest two-thirds across the iliac fossa, backwards and outwards from this through the posterior superior spine, was found. The V-shaped piece of bone included could be moved slightly to and fro. Both surfaces of the iliac bone were bathed by dirty purulent matter. There was wide-spread extravasation among the abdominal muscles at the region of injury.

REMARKS.—In this case was well shown the extensive injury caused by so called "buffer-accidents". On admission, only a small wound existed over the anterior superior iliac spine; this, however, communicating with bare bone. The gravity of the state of affairs was made manifest during the progress of the case and at the *post mortem* examination. Extensive extravasation was followed by sloughing of the tissues; and the drain on the system caused by this and the consecutive absorption of infective material explained the asthenic typhoid condition of the patient. The most interesting fact was the occurrence of a marked double parenchymatous suppurative parotitis, which pointed clearly to a blood-poisoned state, as no anatomical explanation could be given to connect it with the primary injury. It was clearly not embolic; and the nature of the changes in the abdominal viscera and heart, which were softened, but free from infarction or abscess, bears out the theory of its septicæmic character. There was no rigor, nor fever-curves. It may be remarked how severe an injury may be inflicted on the abdominal wall without subsequent peritonitis, so long as the serous membrane remains intact.

## SIR PATRICK DUN'S HOSPITAL, DUBLIN.

CASES UNDER THE CARE OF DR. E. H. BENNETT.

*Operation for Restoration of the Nose.*—We have recently seen in this hospital three cases exhibiting some points of interest in reference to this operation. In the first case, a man aged 24, the operation had been performed on January 17th, 1878; in the second, a boy aged 15, in October 1877; in the third, a middle-aged man, the operation had been performed six years ago by the late Mr. Hamilton. In all three, the disease which had destroyed the nose was lupus; and in all, the disease had been for some time arrested, at least in the part involved by the operation. The method of operation was the same in all, the flap being taken from the forehead. In the management of these cases, Dr. Bennett maintains a slight silver splint beneath the flap, for as long a time as possible, to control the tendency to contraction of the flap and flattening of the new nose. The splint is borne in place until it begins to set up irritation around its edges, in consequence of the pressure of the contracting flap. In the patient operated on by Mr. Hamilton, the columna nasi had been united to the lip, and two nasal openings had been formed; but, in consequence of the contraction, although the nose was fairly good in appearance, the nostrils had been completely obliterated, and the upper lip had been elevated so far as to expose the entire gum; the patient had, in fact, come into hospital to have these defects remedied, particularly that of the lip. In the cases operated on by Dr. Bennett, an attempt to unite the columna was made, but failed, in consequence of the motion of the lip; the feature of the columna was sufficiently formed, but the nostrils communicated beneath it, and an open passage was preserved, without any danger of complete occlusion. The most interesting feature of these two cases was the fact that sensation, at first entirely lost in the flap, was restored in both cases at a remarkably early period. In the case of the boy, a fortnight after the operation; in the man, in the interval between the morning of the eighth and tenth days. Dr. Bennett observed that, in these and in previous cases on which he had operated, the return of sensation occurred suddenly and, as above stated, very early. In the last case, which was the earliest observed by him, in the interval between the eighth and tenth days. It will be noticed that the restoration of sensation in these cases occurred as early as those recorded by Schiff and others, in the direct union of divided nerves; while it is plain that no attempt to attain such exact nerve-adjustment could be made further than such as may follow by an accurate adjustment of the transplanted flap. Division of the neck of the flap, which was made several weeks after the operation, made no change of the sensation-power of the surface of the transplanted flap, even immediately after its section.

*Suppuration of an Ovarian Tumour.*—The patient, a woman aged 35, the mother of four children, was prematurely delivered of twins on the

1st day of 1877, the gestation having reached about the fifth month. After this, the abdomen remained large and was constantly painful. On admission to hospital on February 18th, 1878, the diagnosis of multilocular ovarian cyst was readily made, the tumour being of moderate size. Extensive adhesions of the cyst to the walls of the abdomen and to the viscera of the right hypochondrium were diagnosed, and also a confused solid mass in the left iliac region, in which the body of the uterus could be recognised by examination with the uterine sound. The woman appeared to be in a condition too weakly for operation, and had a constant elevation of temperature, rising slightly in the evening and never falling much below 100 deg. Fahr. in the morning. Operation was declined for the time, and attempts to improve the health were made. The patient was removed to the country for a fortnight, and returned much improved in every respect. A further stay in the country was advised, and again the patient left hospital. In two days' time, she returned with a fresh and more violent attack of pain all over the abdomen. The tumour was observed to have altered in shape, one large compartment of the cyst having become conical near the umbilicus. From this red lines, marking the path of the lymphatics from the umbilicus to the groin on each side, were evident; and it appeared clear from these signs, combined with a marked rise of pulse and temperature, with occasional rigors, that suppuration of part or of the entire cyst had occurred. In the morning of April 16th, the patient got out of bed and suddenly became faint, profound collapse followed, and she died before the following night in great pain from distension of the abdomen. At the *post mortem* examination, the abdomen was found to be distended by purulent matter; the largest cyst of the tumour had burst into the cavity, whilst it was also clearly pointing as an abscess beside the umbilicus. The adhesions diagnosed during life were verified; viz., to the colon and liver, to the abdominal wall in front, and also the adhesion of the omentum and left uterine appendage, and of the uterus in the mass at the left iliac fossa.

*Typhoid Fever simulating Hip-Disease.*—This case illustrates the tendency that typhoid fever has, in its early stages, to assume the characters of very distinct diseases; in this instance, of acute morbus coxae. A girl aged 15 was admitted to the surgical wards under the impression that she was suffering from disease of the hip. She had had violent pain in the hip and thigh for two days, with a hot skin and other features of inflammatory fever. She walked lame, and maintained the limb slightly flexed on the pelvis, resisting any attempt to move the joint. The pain was seated behind the trochanter, and was not complained of when the capsule was pressed in front. Dr. Bennett noticed that, in walking, she brought the heel of the lame limb down to the ground. The exceptional character of the gait and the seat of pain caused doubt as to the disease being acute arthritis. A few leeches relieved the pain, which changed its position to the sacral region. In a few days more, the features of typhoid fever gradually replaced those of hip-disease. The bowels, which had been obstinately confined, being emptied of a large mass of feces, the pain, in a great measure, ceased. The case terminated fatally in the fifth week by hæmorrhage from the bowel.

## TUNBRIDGE WELLS INFIRMARY.

### TUMOUR OF THE BRAIN.

(Under the care of Dr. WARDELL.)

FOR the report of the following cases we are indebted to Mr. J. BULKLEY FOOTNER, House-Surgeon.

A. B., aged 38, a greengrocer by trade, was admitted into Tunbridge Wells Infirmary on March 5th, 1878, suffering from severe pain in the back of the head and neck. Twelve years ago, the patient had syphilis, but had been a fairly healthy man; he was married, and had several healthy children. Two years and a half ago, he fell downstairs, pitching on his shoulder and the side of his head; but he was not stunned, and sustained no scalp-wound.

His illness began two years ago with pain at the back of the head and neck. He felt weak, and had restless nights. These symptoms became worse, and, six months later, he complained of his tongue feeling "too large for his mouth", and was unable to protrude it as far as formerly. He also spoke, as his friends expressed it, as if "his mouth were full of plums".

The secretion of saliva was also greatly increased, necessitating frequent spitting. Nine months ago, he began to suffer from diplopia, due to paralysis of the left external rectus muscle of the eyeball. As he got no better, he was admitted into Tunbridge Wells Infirmary. On admission, he was seen to be an emaciated man, looking older than his years warranted. He complained of a severe pain situated at the back of the head and radiating down the back of the neck to both shoulder-

blades. This pain was seldom absent, but was aggravated at night, and greatly increased by the recumbent posture.

There was complete paralysis of the left external rectus muscle of eyeball, and slight ptosis of the same eyelid. The velum pendulum palati was paralysed and drooped on the left side, and the uvula was deflected to the right. The tongue was exceedingly soft and flabby, and the patient could not protrude it beyond the teeth. The mouth was full of a viscid saliva. He was unable to turn his head without moving his body at the same time; nor could he raise his right arm above his head. A tumour, some deposit, or thickening at the base of the brain was diagnosed, and, as it was suspected to be of a syphilitic character, iodide of potassium was administered in fifteen-grain doses, without, however, any beneficial effect. Sedatives were also given to allay pain.

The patient remained in the infirmary about one month, and then, as he was no better, went home to his family. While there, the pain became more intense and unbearable, and the patient's tendency was suicidal. He suffered from cough and dyspnoea during this time. Five days after leaving the infirmary, he suddenly complained of a suffocating sensation in his chest, and asked his wife for a mustard poultice. She went out of the room to get it, and, when she returned, he was dead.

*Post Mortem Examination.*—On opening the head, the walls of the skull were found to be enormously thickened—nearly half an inch in thickness. The dura mater was very adherent. There was a quantity of serous fluid in the cavity of the arachnoid and ventricles of the brain. The brain-substance was healthy. On its removal, there was seen to be a tumour of the shape of a horse-chestnut, and double that size, situated beneath the dura mater, on the anterior and left lateral margins of the foramen magnum, projecting upwards into the cavity of the skull, and extending down the vertebral canal. By its pressure, the upper part of the spinal cord and medulla oblongata was flattened and pushed to one side. On cutting into it, the contents were found to be grey curdy pus, with several sequestra lying loose in the cavity of the abscess. The largest of these sequestra measured one inch long and half an inch broad. The bone round the cavity of the abscess was soft and carious. Neither the cavity of the thorax nor the abdomen was examined.

## REVIEWS AND NOTICES.

FIVE YEARS' SURGICAL WORK IN THE MANCHESTER ROYAL INFIRMARY. By EDWARD LUND, F.R.C.S. London: Simpkin, Marshall, and Co.

IN this little work, Mr. LUND has presented to the profession five years' surgical work in the Manchester Royal Infirmary.

The author justly merits the reward due to honest labour and perseverance—labour which can only be estimated when we state that the subject matter contained is deduced from the notes, fully and accurately taken, of over thirteen hundred cases. The author has classed the different subjects under eight different heads, and has formed other classes by dividing and subdividing according to the different facts which they tend to establish.

Some of the subjects considered by Mr. Lund are of great importance in a surgical point of view, and would demand more than a passing notice; and it is almost to be regretted that their association with statistics may deter some readers from their perusal. Statistics require a singular genius to make them interesting; and yet it is in this respect the author is so happy, for, without obvious servitude to a numerical system, the cases are arranged on a plan convenient for practical suggestions and comprehensive deductions.

It is a glaring defect in any hospital, and much to be regretted, that it should devolve on any member of the honorary staff to compile statistics—a duty, it would appear, which ought undoubtedly to be conducted by one whose province does not in any way make him responsible for the treatment of the cases; but, in the absence of such provision, Mr. Lund leaves nothing to be desired in the example he has laid before the profession.

If it were possible to obtain from every hospital surgeon an equal number of statistics as valuable and as available, we should soon possess a great mass of useful matter; whereas it appears to be rather the exception than the rule for surgeons personally to garner the results of their labours, and consequently they leave not wholly accomplished their duty to themselves and to those to whom they owe their position. It is more particularly on this account that we would congratulate Mr. Lund, as he confesses that such feelings largely influenced him in the publication of his work.

ON ASTHMA: ITS PATHOLOGY AND TREATMENT. By I. B. BERKART, M.D., Assistant-Physician to the City of London Hospital for Diseases of the Chest, etc. Pp. 264. London: J. and A. Churchill. 1878.

THIS work is a valuable addition to the literature of asthma, and will be widely read at the present time as an earnest and erudite protest against the validness of the long prevalent theory that asthma is a nervous affection, and in particular a bronchial spasm. Dr. BERKART adds the weight of his reasoning and experience to the view that the asthmatic seizure is due to other and deeper causes than bronchial spasm, e.g., to emphysema with bronchial accumulations, to inflammatory thickening of a portion of the lung, etc.

The history of the literature of asthma is, as may be seen in the interesting early pages of Dr. Berkart's work, an alternate affirmation and denial of the proposition that the malady is one of disordered innervation. Laennec, in the light of whose great discovery all chest-diseases were reconsidered, accepted purely spasmodic asthma as one of the several varieties of the disease, the other forms being those recognised pulmonary affections, in the course of which paroxysmal dyspnoea was of common occurrence. The absence of physical signs and of adequate *post mortem* evidence of pulmonary disease in cases—and most particularly in one case—of fatal dyspnoea, led Laennec and Andral to the admission that asthma arose in certain instances solely from deranged innervation of the lungs and bronchi. The subsequent demonstration by Dr. C. J. B. Williams of the muscular irritability of the bronchial walls to the electrical current, and the further observation of Longet that irritation of the pneumogastric nerve would also cause the bronchial tubes to contract, gave strong support to the muscular spasm theory. And this theory, notwithstanding many counter-experiments and denials, has, on the whole, firmly prevailed to the present day. In his endeavour to disprove this view and to place the disease on a wider and more distinctly pathological basis, Dr. Berkart shows great ingenuity of argument and extended reading. According to Dr. Berkart's definition, "the antecedents and sequelæ of asthma manifest themselves as one continuous though protracted pathological process". Hence, "asthma is only one link in a chain of quasi-independent affections, which commences with inflammatory changes of the pulmonary tissue, and terminates with emphysema and bronchitis". The antecedent disease is, in the majority of instances (80 per cent.), a bronchitis or catarrhal pneumonia, commonly consequent upon measles or whooping-cough. The sequelæ of asthma are bronchitis and emphysema. Asthma itself is, the author maintains, but a symptom dependent upon pulmonary lesions the result of past inflammatory attacks, or upon more insidious changes of a prematurely senile or degenerative kind. The constitutional condition most favourable to the production of asthma is the rickety. Such we gather to be the author's view of the pathological position of asthma.

The immediate causes calling forth the attacks are numerous and of various kinds; but, whether by pulmonary hyperæmia, bronchitis, or direct blocking, they are all productive of the same result—obstruction of the bronchi.

Respecting the morbid anatomy of the disease, the author has necessarily very little to say that is strictly in point. Death from asthma is the rarest of occurrences, and no *post mortem* examination of a simple and genuine case seems to have been as yet recorded. The case of fatal dyspnoea which served to convince two such accurate observers as Andral and Laennec of the occurrence of purely spasmodic asthma is—we think somewhat rashly—set aside by the author as in all probability one of embolism of the pulmonary artery. A small portion of the base of one lung was, it is true, described by Andral as in a state of pneumatic consolidation, and the clinical history of the case might favour the diagnosis of embolism; but when such an observer as Andral emphatically states that the lungs were with this exception healthy and crepitant throughout, one must conclude that some other condition was present during life to account for the severe and sustained dyspnoea which yet left no trace behind. And, in denying altogether the operation of a nervous agency in asthma, lies, we think, the weak point in Dr. Berkart's argument. He forces us strictly to compare the symptoms during life with what we know or may conjecture of the morbid conditions actually present. In doing this, we are confronted with the fact—difficult to understand from the point of view which altogether excludes perverted nervous agency—that the paroxysms of dyspnoea are quite as severe at the early as in the later periods of asthma, whereas coincidentally and keeping pace with the development of those recognisable lesions of the lungs and heart to which the patient finally succumbs, we get persistent and ingravescent symptoms of a definite kind. And the prognosis of the disease—at least, in its typical varieties—is more favourable than one

could hope for in a degenerative disease of a vital organ. Dr. Berkart truly observes, p. 204, that "the prognosis as to life is in general favourable", especially in the atrophic or emphysematous form, in which the patient may live to an advanced age. Must not the lungs be in at least an average degree of textural integrity in the first instance in such cases to withstand the repeated strain of the asthmatic paroxysm for so long a period? In the "hypertrophic form of the disease", on the other hand, in which interstitial pneumonia of an insidiously progressive kind is the lesion, the symptoms of phthisis soon appear and destroy the patient.

The author strikes the first key-note of all treatment at the same time that he would seem to exclude the asthmatic seizure from being necessarily dependent upon molecular or inflammatory changes in the lungs, when he remarks that, "upon the whole, it may be said that every asthmatic seizure is more or less a preventable accident, so that an efficient and suitable prophylaxis is almost tantamount to a cure".

We must, in conclusion, express our strong approbation of this book as a good honest piece of work. In every page, we find evidence of extensive reading; and, although, as we have very imperfectly pointed out, we cannot admit that the author has yet quite demolished the nervous theory of asthma, he has nevertheless, with great ability and no small success, striven to place the pathology of the disease upon a more material and secure basis, and to render its treatment less haphazard and fanciful.

## SELECTIONS FROM JOURNALS.

### THERAPEUTICS.

TOLERANCE OF OPIUM BY AN INFANT.—Dr. J. L. Little reports (*American Jour. Obstet.*, April 1878) a case where paregoric in small doses was administered to a child three weeks old for the relief of suffering caused by an inflammation of the knee-joint. The child gradually bore larger and larger doses; the paregoric was changed to tincture of opium, and this again to Magendie's solution. Soon the child obtained such a tolerance of this drug that, in a couple of months, from half a drachm to a drachm a day was necessary to quiet it. This state of things continued until the amount consumed by the child, then less than eight months old, was two ounces of Magendie's solution in twenty-four hours. The dose was gradually diminished at the rate of about three drops per day, and, at the time of making the report, but ten drops were given at bedtime. The child's appearance improved very much; it was intelligent, and weighed eighteen pounds.

ABSORPTION OF IODIDE OF POTASSIUM BY THE VAGINAL MUCOUS MEMBRANE.—J. Smolski (*Petersburg. Medicin. Wochenschrift*) finds that iodide of potassium is very rapidly absorbed by the mucous membrane of the vagina, when introduced in large doses in the form of globules with cacao-butter. In twelve hours, of twenty grains, eighteen were absorbed; on the other hand, only two grains and a half out of ten were absorbed. The absorption of a solution in glycerine is slower. Of a solution of twenty grains in about two drachms of glycerine, only two grains and a half were absorbed in twelve hours; and of a ten-grain solution, only one grain and a half in the same time. The rapidity of absorption may be increased by the addition of free iodine.—*Centralblatt für Gynäkologie*, June 8th.

TREATMENT OF CROUPOUS PNEUMONIA BY COLD.—In a paper read before a medical society in Sweden, Dr. P. A. Lewin recommends the local application of cold in croupous pneumonia. He published a memoir on the subject in the *Hygiea* in 1862. Among the numerous advantages of the plan, he signals the immediate cessation of the oppression and shortness of breath, which may become aggravated under the internal use of antipyretics. The most suitable way of applying cold is, according to the author, the following. A small—and preferably a torn—soft handkerchief is dipped in water at a temperature of 8 to 12 R. (50 to 59 Fahr.), and is then squeezed (not wrung) until the water no longer runs from it when held up; it is then folded up six-fold and laid on the front of the chest—a coarser handkerchief being placed below it to prevent the water from running over the body. The application is removed at intervals varying from eight to twelve or twenty minutes. Water of a lower temperature than that above mentioned must not be used: the handkerchief must be changed or entirely removed whenever a rigor is felt, and not reapplied until the rise in temperature demands it. This method of applying cold renders unnecessary the use of general baths in pneumonia.—*Allgemein. Medicin. Central-Zeitung*, April 6th.

## BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

## BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 22ND, 1878.

### THE TWO MEDICAL ACT AMENDMENT BILLS.

THE present and succeeding weeks will probably mark an important epoch in medical legislation. Two Bills to amend the Medical Act of 1858 are now before the House of Commons. The first was introduced into the House of Commons by Mr. A. Mills, Mr. Childers, and Mr. Goldney, and ordered to be printed on May 29th. The second was brought from the House of Lords on June 7th, 1878, and ordered to be printed by the House of Commons on June 13th. The latter is the Bill of the Lord President. This Bill has been much modified in its passage through the Lords. It was introduced into the House of Lords and ordered to be printed on March 19th. This Bill, as it then stood, was objected to by the British Medical Association on the ground of its not enforcing compulsory conjunction for examination of all the medical authorities in Scotland and in Ireland, and thereby placing the English medical authorities at a disadvantage which must have proved injurious to them. It also omitted to provide for the representation of the profession in the General Medical Council. Under these circumstances, the Medical Reform Committee expressed their determination to oppose the Bill. They canvassed the profession; and on May 18th they again waited on the Lord President, and informed his Grace that the result of 5,227 replies was:

	AYE.	NO.
Direct Representation . . . . .	5,075	121
Conjoint Scheme . . . . .	4,910	264

Replies have continued to come in since the above result was announced, and have only yielded one additional No; the Ayes, with that exception, being unailing. On this occasion, the Lord President assented to compulsion as regarded the corporations, but insisted on leaving the universities free. Further than this his Grace declined to go towards the establishment of the long demanded uniformity of qualification. At this stage, the Medical Reform Committee had, therefore, no other alternative than the introduction of the Bill of the Association, which was brought into the House of Commons and ordered to be printed, as already stated, on May 29th. The Lord President, however, further amended his Bill in the House of Lords, and it was ordered to be printed as amended on May 24th. On recommitment, it was again modified and ordered to be printed on June 3rd, five days after the introduction of the Bill of the Association, with a conjoint scheme similar in its effects to that embodied in the Bill of the Association. The Bill of the Lord President, as thus framed, establishes for the first time a conjoint board on the principle contended for by the Association. It also gives the General Medical Council greater powers than it has hitherto possessed, and assigns them the duty of framing examination-rules for the conjoint boards—a duty from which the General Medical Council shrinks, as proved by the resolution quoted in our article in the last number of the JOURNAL (June 15th), to the effect “that the duties of the Medical Council.....should not be extended to the initiation of the examination-rules under which qualifications are to be granted”: a very remarkable resolution for a Council, so called, of Medical Education.

The Bill of the Association (Medical Bill No. 2) would further make the Medical Council more independent of the Privy Council than the Bill of the Lord President; but, before giving it such increased powers, regards its modification so as to make it representative of the profession as well as of the universities and corporations, and of the Government, imperative. This is the cardinal point in which Medical Bill No. 2 differs from that of the Lord President; and it is as representing the approval of the almost united voice of the profession that Medical Bill No. 2 is supported by such numerous petitions, while there are none from the profession against it.

In 1857 and in 1858, it was the British Medical Association and the profession that carried medical reform in the face of opposition from prejudiced and interested corporations; it will, indeed, be strange if, in the present day of representative government, the voice of the profession be disregarded. It is proposed to fix the expense of the election of the representatives of the profession on the funds of the Medical Council. In this respect, it must be borne in mind that the profession has supplied the whole of the funds which have supported the Medical Council and paid the delegates of the rich universities and corporations, while wasting time, year after year, in discussions in which the interests of the universities and corporations they were appointed to represent were alone involved; while, as regarded measures of great public utility, such as the conjoint scheme of examination, their deliberations were inoperative. Had it rested with the representatives of the corporations, the small majority of fourteen to ten by which the resolution in favour of a conjoint scheme was carried during the last session of the Council would have been converted into a majority against it. The votes of the Crown nominees alone turned the balance in its favour.

The opponents of the representation of the profession resort to every device to oppose it. It has been suggested that the number of the Crown nominees should be increased with that object, but this in no way meets the views of the profession. The profession desires that the Council should rest on the widest possible basis; that it should continue to represent the time-honoured Universities and Corporations of the land; that it should represent the Crown; that it should also represent the profession. The Crown nominees must frequently, if not always, be to a great extent the nominees of one man, not improbably of the medical man who, whatever his creed, may happen to possess the ear of him who nominates. The late Emperor of the French held a homœopath in high esteem; and, to come nearer home, it has been reported in the daily papers that the Lord Chancellor of England, notwithstanding his commanding intellect and unsurpassed attainments, presided at a meeting in favour of a homœopathic hospital in this country. With such knowledge at our hands, it is quite conceivable that the medical adviser of the Privy Council may, at some period, hold similar heretical notions; and in such case, it is certain that such influence could only be prejudicial to the scientific development of medicine.

The statement has further been made that all the members of the Medical Council, as at present constituted, represent the profession. How this assertion can be maintained in the face of the fact that for years the profession has demanded the conjoint scheme, and that the majority of the representatives of the corporations on the Council have done their best to refuse it; that the profession has for years demanded representatives elected by the general suffrage of the profession, and the Council has never once seriously discussed the propriety of conceding them—how, under such circumstances, such an assertion can be maintained certainly passes ordinary comprehension; for, instead of representing the profession, the Medical Council has thus persistently placed itself in opposition to its united voice.

What, under these circumstances, has the Medical Council done for that profession which has supplied it with funds to the extent of something like £150,000? It has given the profession the *British Pharmacopæia*,

a publication which, with exclusive right of sale, probably any publisher would gladly have undertaken for £500, certainly for £1,000; and it has compiled a *Medical Register*, which the enterprising publishers of the *Medical Directory* successfully compete with as a private venture. The sooner the General Medical Council, which has received so much and has given so little, is effectually reformed the better. Crown nominees and corporation delegates do not represent the profession; and it is for this reason doubtless that the profession supports Medical Bill No. 2.

### MEDICAL EXPERTS AS WITNESSES IN COURTS OF JUSTICE.

UNDER this title, a member of the United States bar has published a paper containing much useful information on the duties of experts or scientists.\* Medical and scientific experts are now so frequently summoned to give evidence in our English Courts, that it may be useful to extract for their information some remarks on their duties, liabilities, emoluments, etc. The practice in England and the United States is similar, so that the rules laid down by Mr. Ledergerber are equally applicable to English experts.

The evidence required from experts is that which is based on *opinion*. Certain acts or circumstances are hypothetically stated, and the expert expresses his opinion on the conclusions to which they lead. The sole object of this testimony is to throw light upon the subject of the inquiry, and to aid the jury in coming to a just verdict. Experts are not allowed to take the case from the jury and give an opinion on the point at issue, which the jury alone have to decide. Thus, in a case of stealing an article of value, an expert would not be allowed to state that the taking was an act of insanity. He can only state that, from all the facts, it is his opinion that the accused was probably labouring under a fit of insanity at or about the time of the taking. If the jury believe him, the inference is the same, but the jury only can find the fact and act upon it. In spite of the opinion of the expert, the jury may find that the accused was sane at the taking and responsible for the act.

Experts are the only witnesses who are permitted or compelled to testify in a case, the facts of which are unknown to them, and which they have not heard detailed by other witnesses. Hypothetical cases are put to them, and they are compelled to state their opinions as to the probable result. If an expert give an opinion upon facts witnessed by himself, he must state clearly the facts upon which he bases it. In this case, he becomes an ordinary witness. When a certain state of facts is laid before him, he is not allowed to alter or modify them in any way, but he must deliver his opinion on them as they are put before him by counsel. The facts upon which an opinion is based must be undisputed, and not put in the alternative; for opinions on different states of facts would not assist the jury. This is one cause of conflicting medical evidence at trials. The solicitors for the plaintiff and defendant will often draw up different statements of facts, relating to the same case, and then obtain the opinions of experts, which of course when given at the trial appear irreconcilable. It is for the jury to find the true facts, and then apply the opinions which have been given upon them. No opinion can be given on a part of the facts in the case.

There are some points which it is not in the power of an expert to answer. He may be asked whether a certain wound had been produced by a weapon also produced in evidence. There are so many weapons of a similar kind, adequate to produce a similar wound, that he could not assign it to any one, nor could he say whether a fracture of a skull produced in evidence was from a weapon also produced. There are many cases not proper for an opinion; and, as a rule, that which is evident or comprehensible to persons of ordinary understanding cannot be the subject of an opinion for an expert.

One of the difficulties connected with the evidence of experts in the

English and American Courts is that which relates to partisanship. Lord Hatherley says on this point: An expert who gives an opinion is selected by the litigant, and when so selected, he is expected to express and adhere to that particular opinion which is favourable to the case of the person who summons him. His Lordship observes: "He" (the expert) "honestly entertains it, I doubt not, when first selected; but then it is like a counsel's opinion. The counsel gives his opinion on a statement of facts submitted to him; but perhaps, after hearing the other side, he would find the case wholly altered, and would say so. But the expert, called into court by the plaintiff, is generally expected to support his case in cross-examination, when many views may be suggested that may greatly modify the witness's judgment; but even after facts have been proved that really ought to modify it, the expert frequently holds to his original opinion. Every expert should eschew altogether the notion of partisanship. He should be ready frankly and unreservedly to give his opinion regardless of how it may tell. He is there, not as an advocate, but in order to inform the jury according to the best of his judgment."

Lord Hatherley expresses a doubt whether any evidence of *opinion* (i.e., of experts) should ever be received on oath. The jury would then see that it was opinion only that was given, and deal with it accordingly. This great legal authority would only allow experts to be called by the judge, and not selected as now by either litigant.

Mr. Ledergerber, in dealing with this question of partisanship, observes that, in France and Germany, it has received a solution more satisfactory to Court and counsel than under the English laws relating to evidence and witnesses. In those countries, experts are called by the Court to investigate the subject of inquiry upon which their testimony is required. They are clothed with the authority of the Court during their investigation, and report to the Court only; and unless bias, fraud, or partiality, be shown, the Court adopts their opinion as the rule of law in that case. They cannot well become partisans for one side, for neither side calls them. "Under the English and American systems, it frequently happens that a number of experts are subpoenaed on each side, and, strange as it may seem, a majority give their opinions favourable to the party calling them, and it seldom if ever occurs that one of them will say he is not thoroughly prepared or competent to give an opinion on the question propounded. The tendency of this is to detract from the value of such opinions in the eyes of the juries and the bar. 'Who shall decide when doctors disagree?'"

Opinions of experts are to be received and weighed by the jury, and their credibility considered in the same manner as other evidence.

Any man who has attained a reputation for knowledge in any branch of medicine or science may be summoned to give evidence as an expert, although he may know nothing of the facts of the case, or he may not have been previously consulted. No litigant, however, would act upon this rule, unless he knew, from the published or expressed opinions of the expert, that his testimony would be favourable to his case. By permission of the Court, he may be treated as a hostile witness, and cross-examined by the counsel who summons him.

The late Lord Campbell ruled that an expert, who can give only evidence of *opinion*, should not be subpoenaed, and was not bound to obey a subpoena. If, however, he can testify to any *fact* in the case, he must obey the legal mandate. The safe course for an expert is, however, to obey a subpoena under all circumstances. Then arises the question of fees. Mr. Ledergerber remarks that the German and French Courts award to all experts suitable compensation. This is not the case in England and the United States. Unless an arrangement be made on receiving the subpoena, there is usually great difficulty in procuring reasonable compensation, especially in criminal cases. On these occasions, an expert who can testify to *facts* must obey a subpoena, be sworn, and give the necessary evidence. If, however, he have been summoned only for evidence of *opinion*, he may decline to be sworn or to give this evidence until he has received his proper fees, or a guarantee for their payment: and, as a rule, our Courts will uphold

\* Article xxviii, *St. Louis Journal*, by F. T. Ledergerber, Esq.

this conduct on his part. It would seem that the practice in the American Courts is similar. Thus, Mr. Ledergerber tells us, that Dr. Dills and Dr. Buchanan of Fort Wayne, Indiana, were on one occasion fined for refusing to give their professional *opinion* in a criminal case, in Allen County, without having been first paid or promised due compensation. They appealed, and the Supreme Court sustained their objection, and reversed the decision of the Lower Courts. It would, indeed, be a gross piece of injustice to force men, eminent in any department of medicine or science, to give their professional opinions without receiving proper compensation.

### IRISH LUNATIC ASYLUMS.

THE *Dublin Daily Express* of May 24th contained an excellent article on the comparative usefulness of visiting as opposed to resident assistant-physicians in the Irish lunatic asylums, and discusses the subject in such an impartial tone, that we recommend its careful perusal to all those interested in the future of lunacy in Ireland. This is not the first occasion on which our contemporary, one of the leading Dublin journals, has manifested its interest in the well-being of the insane of the sister isle, for it quite recently devoted an exhaustive leader to the same subject; almost reiterating, however, much of what has appeared in these pages from time to time, especially in the *JOURNAL* of March 16th, when we wrote: "For the offices of visiting physician and apothecary—offices now almost extinct in the English pauper asylums, and in many cases, we fear, little more than a sinecure in those in Ireland—might very advantageously be substituted that of assistant resident physician." We would now again urge on the authorities the desirability of such a change, which could be secured without additional outlay. We find that the salaries of the former vary from £100 to £160, and upwards, while those of the latter range from £30 to £100 *per annum*; and we are sanguine that an office combining as pay the remuneration of the two in question would secure eligible applicants, and, for many reasons, be most advantageous.

We would ask, how is it possible for the medical chief of an Irish asylum, with his present numerous and varied duties, to keep his case-books with that minuteness of detail as to the past personal and family history of his patients, to record the varying phases of a very variable malady, without which he is to a large extent groping in the dark; or to treat with scientific accuracy a disease which, originating in the most complex, obscure, and hidden organ of the body, may ultimately involve the whole nervous system? The very obscurity of the disease ought to demand and obtain for it the most careful study for its successful treatment, and certainly not such as can be accorded to it in the hurried, irregular, and occasional visit of a consulting physician. How, again, can one already overwrought brain possess the will for the study necessary to keep pace with the enlightened advance in the treatment of the insane of the present time, leisure for that pathological investigation of the disease so highly prized by those alienist physicians who have an opportunity for such, or recreation to ensure him *mens sana in corpore sano*? Till the superintendents of the Irish asylums are relieved of some of their present duties, by the appointments of resident medical colleagues, we cannot expect to see any improvement in the mode of keeping the medical records of those institutions. The Commissioners in Lunacy in this country are very particular, not only as to the full and frequent reporting of the cases, but also as to the performance of *post mortem* examinations, doubtless with the double object of the study of the disease and the discovery of injuries, *e.g.*, fractured ribs, which might otherwise remain latent; and why should there not be a like necessity for such in Ireland?

Such a change as we advocate would also have the tendency to increase the general knowledge of insanity, and bring the lay public to regard it as a distinct disease, requiring, and capable of cure by, early

medical treatment, instead of a loathsome curse to be screened by all means, however barbarous,—an outrage on civilisation,—and till the malady has become chronic. We fully endorse the views of our lay contemporary as to the advisability of having a consulting physician to the larger asylums, so situated that the most skilful advice can be obtained when necessary; but we are of opinion that he should be chosen on account of his general medical and surgical knowledge, with a view to his being consulted in complications arising in the course of insanity, leaving the treatment of the special disease to the specialist. The appointment of such an officer, as also of the assistant-physicians, should be in the hands of the Government. With regard to the argument that the visiting physician is requisite as a means of communication with the outer world, we ask, why more so in Ireland than in England? In both countries, the friends, as visitors, have free and frequent access to their confined relatives; whilst in Ireland, the visits of their spiritual advisers are more numerous; for in that country there are invariably a Protestant, a Roman Catholic, and frequently a Presbyterian chaplain, against the one of the former faith in this. Moreover, the visits of the inspectors to the Irish asylums are much more frequent than those of the Commissioners in Lunacy to their charges.

If this argument be advanced with the object of showing that, from his overworked condition and multifarious duties, the medical superintendent is liable to overlook the restoration to sanity of one of his patients, so that he shall be unjustly incarcerated, then we hold that it strengthens our case; for it is evident that an intelligent resident medical assistant, almost constantly associated with his patients, and thoroughly conversant with their peculiarities and eccentricities, is much more likely to bring to the knowledge of his chief such recovery than would a casual visiting physician. Again, we think such chance would be entirely obviated, if the Boards of Governors would occasionally devote some of their time to visiting the wards of the asylums and conversing with their inmates, rather than in discussions tempered by political and religious excitement.

But if the argument be advanced on the more unwarrantable ground, insinuating connivance at the detention of the insane from personal interest, then we consider it so base and unworthy of its source as not to need refutation.

Finally, in the occasional temporary or more prolonged absence of the medical superintendent from his asylum, whether on leave or on duty, as things exist at present, the institution must frequently be left without a responsible medical head for almost entire days together; and who, with any practical knowledge of insanity or its treatment, will assert that this, from a medical point of view, can be otherwise than highly unsatisfactory and unsafe? For it is well known that in this disease, perhaps more so than most others, various complications may at any moment arise, requiring immediate medical attendance. Again, the responsibility for the general management and control of the discipline of the establishment in that case generally devolves on the matron, who, we think it will be conceded, is scarcely the person to conduct the administration with satisfaction, or to the best advantage either of the patients or of the ratepayers.

THE death of Marshal Baraguay d'Hilliers is announced to have taken place from an error in swallowing a poisonous medicine. Under what circumstances the mistake was made, does not appear.

A NEW Children's Hospital was opened in Dresden on May 31st. It is situated in one of the most elevated parts of the city. The ground-floor is divided into six wards, containing in all thirty beds. The upper floor has eighteen beds, and is intended at present for cases of infectious disease.—A hospital has also been established at Kreuznach for the reception of children. It consists of two large wards, each with thirty beds. There are also a room for meals and a playground.

We publish this week a series of papers on the subject of vaccination and its methods, of which the capital importance will be at once apparent, and which are opportune at the moment.

A NEW view of the real object of the doctors in supporting compulsory vaccination is set forth in a document which is being widely circulated in London. It is a device for political purposes of despotism, having a Russian origin. This is as reasonable a theory as many others that are set out by Mr. Hume-Rothery and his friends.

IN the House of Commons, on Tuesday night, Mr. Cross replied to Mr. Jacob Bright that he knew nothing of the particular circumstances of the imprisonment of Mr. Clarke of Ironville, Derbyshire, for refusing to vaccinate his child; but when a man was sent to gaol, for whatever offence, he was treated, in respect to receiving letters and communicating with his family, like all other prisoners.

A SUM of about £10,000 has now been promised towards the funds of the Home Hospitals Association. This is the minimum which it was announced at the first meeting of the founders at the Mansion House would be considered adequate to the commencement of active operations. A suitable house is now being selected for the purpose of opening a home hospital for acute surgical and medical cases.

AT this stage, the Honorary Secretary, Mr. H. Burdett, intimates that the time has arrived for proceeding to fill up that further part of the programme which was expressly stated at the outset, and which consists in the provision of "isolation houses" for middle-class convalescents from infectious disease. He points out once more that, at the present time, a member of a middle-class family, after safely battling with fever or other infectious disease, arrives at the stage when disease has ceased and health has to be restored, where can the doctor send him, and without danger to the rest of the community? Under these circumstances, the Home Hospitals Association propose to open convalescent homes for the upper and middle classes, which will combine the comfort of a home and an hotel, in which the cost of residence and attention will be cheapened, and where patients recovering from infectious diseases will be able to procure every requisite accommodation for a reasonable but remunerative payment. Nor is this all, for the association will arrange for the removal of the convalescent from his own home to the seaside; that is to say, they will undertake to send a proper conveyance for his removal to and from the station, and to procure the needful isolation during the railway journey. In this way, it is hoped that good service will be rendered to the public, the medical profession, and the patients themselves. And he adds that, when £5,000 is specially subscribed—many people have written to say they will give to the convalescent branch of the scheme—the Home Hospitals Association will be prepared to open a home or homes for convalescents without further delay. We are inclined to regard this as by no means the least useful part of the work of the association.

A CONFERENCE of representatives of London local sanitary authorities was held on Wednesday at the Cannon Street Hotel, with reference to the proposed provision of hospital accommodation for cases of infectious disease for other than paupers. After some discussion, a resolution was passed setting forth that provision should be made by Act of Parliament for one authority, acting for the whole metropolis, to provide hospital accommodation for non-pauper persons suffering from infectious or contagious diseases.

THE fiftieth anniversary of the opening of University College falls within this year. It is intended to celebrate the occasion by a gathering of members of the corporation, present and past professors and masters, old students of the College and School, and other friends and benefactors of the institution, to be held within the precincts of the College, on Tuesday, July 9th, at 1 o'clock P.M. The Right Hon. Earl Granville, K.G., Chancellor of the University of London, has kindly accepted the invitation of the President, Council, and Senate

to attend and lay the first stone of a further much needed extension of the College buildings, and preside at the luncheon; and the presence is expected of many other persons of distinction, interested in the welfare of the College and in the promotion of university education.

DR. F. T. ROBERTS, the author of the popular *Handbook of Medicine*, and Assistant-Physician at the University College Hospital, has been nominated Professor of Materia Medica and Therapeutics in University College.

A PUBLIC meeting will be held at the Assembly Rooms, Eyre Arms, Hampstead, on Friday evening, June 21st, to consider the question of the present epidemic of diphtheria in the district. Professor Huxley, F.R.S., will take the chair at eight o'clock, supported by the Rev. Canon Duckworth, M.A.

FOUR cases of cholera have occurred in the House of Correction in Marseilles. One has resulted in death; the other three are on the way of recovery. No further case has since been remarked in the whole Department of Bouches-du-Rhône.

ACCORDING to Professor Hedenius of Upsala, there is a remarkable peculiarity in Sweden in regard to the distribution of the forms of tapeworm. In the south of Sweden, the *tenia solium* prevails; while in Norrland and Upland the *bothriocephalus latus* is most frequently met with. The specimens of tapeworm in the anatomical and pathological museum at Upsala, obtained from the town and neighbourhood, are almost exclusively bothriocephali. Dr. Hedenius has found the *tenia mediocandata* only once in Upsala.

IT had been announced that, since the recent determination of the University of London to admit women to graduate in all the faculties, the classes of University College, London, were open to ladies. Mr. Tal-foord Ely, Secretary, writes from University College, Gower Street, June 18th: "To prevent misunderstanding, I shall feel obliged if you will inform your readers that the admission of women to classes in this College does not apply to the Faculty of Medicine, but only to the Faculties of Arts and Laws and of Science."

SINCE the return of M. Alphonse Guérin to Paris, this eminent surgeon has delivered, at the Académie de Médecine, an address on the treatment of wounds which has produced a marked impression. M. Guérin has, it is well known, long practised an antiseptic method of dressing, which consists in careful and minute cleansing of wounds by a stream of carbolic water (with a strong solution of twenty per cent. of carbolic acid), and their subsequent envelopment in thick masses of fresh cotton-wool; this acts as a filter, excluding septic germs. The method, which precisely accords in plan with Pasteur's first experiments and Tyndall's subsequent verifications, gives admirable results, of which he gives details. M. Guérin gives his impressions of the Listerian method, which have been agreeably modified by his personal inspection of them, and renders full justice to the method, which carries out in perfection the antiseptic principle. He refers also to the good results of Mr. Callender with simple carbolic dressings, applied with great care as to isolation of dressings, absolute cleanliness, and attention to the details of the patient's condition. The answer to the objections to the antiseptic principle in surgery is very complete; and indeed, so thoroughly has the opposition to this method broken down in France, that we may necessarily expect to see a rapid development of Listerism in the French hospitals, and a correspondent decrease in the mortality from pyæmia, abscess, erysipelas, etc., which till lately offered so habitually shocking a spectacle to the surgical visitors to those hospitals.

BEFORE, however, the French hospitals are restored to a level with the hospitals of England, Germany, and America in this capital particular, a great reformation must be made in the system of nursing and dressing. Skilled nursing is rather the exception than the rule, according

to common experience, in the French hospitals. The nursing sisters are well trained, or not at all; they are too long absent from the wards; they are too much occupied with religious observances, administrative work, etc. The dirt and neglect of the patients visible in almost every French hospital which we have visited are such as would make the English stand on end of cleanly, well trained, and attentive English nurses. The dressing, too, is much neglected. It is performed irregularly, with insufficient regard to cleanliness, punctuality, and system, and too much with insufficient regard for the comfort of the patient. The impression of French hospitals, surgical and medical, has often given us a headache, from the spectacle of the unjustifiable neglect of the patients by the nurses and the badness of the dressings, and the unnecessary sufferings inflicted from these causes and from the want of a proper supply of hospital appliances.

In the following case, it seems clear that life could have been saved by the precaution which we have often urged upon pharmaceutical chemists, of dispensing poisonous medicine and lotions for external application. Some days ago, Mr. W. Codd held an inquest at Falkbourn H<sup>l</sup>, near Wisham, on the body of the Rev. W. Bullock. He was busy superintending some packing and other preparations for a visit to London, when he felt fatigued and unwell, and went to a cupboard where he had medicines, intending to take a dose to revive himself. In the cupboard, standing beside his medicine-bottle, was a bottle containing a poisonous lotion, with the label turned towards the wall; and unfortunately he mistook the bottle for his medicine, and swallowed a dose before finding out his mistake. Quickly afterwards, however, he discovered his error, and immediately despatched a messenger for Dr. Tomkin, meanwhile taking emetics to counteract the effects of the poison; but before the doctor arrived Mr. Bullock died. A verdict of "Accidental death" was returned.

MR. RICHARD DAVY has resigned the office of Surgeon to the Surgical Aid Society—a society of which the excellent objects are much impeded, as we have lately several times insisted, by its defective lay administration and the hardships thus inflicted on those who seek its benefits.

#### APOTHECARIES' SOCIETY v. WIGGINS.

MR. R. H. S. CARPENTER requests us to state that the above case, on the importance of which we commented last week, belongs entirely to the Medical Defence Association, of which its founder, Mr. George Brown, is the indefatigable honorary secretary. The Medical Alliance Association has brought to a termination twenty-seven prosecutions; but it is not entitled to any share of the great credit attaching to the prosecution of this case.

#### CHOLECYSTOTOMY IN DROPSY OF THE GALL-BLADDER.

A *factum* of Dr. Marion Sims's case of cholecystotomy for dropsy of the gall-bladder, published in the JOURNAL of June 5th, Mr. George Brown of Colebrooke Row writes to say that, in January last, he operated in a somewhat similar case; and that the patient, a female, has so far recovered as to be able to walk out and to attend to her household duties. Mr. Brown has promised us further details of the case for publication in an early number.

#### METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of this Fund was held on Wednesday, in the Venetian Parlour of the Mansion House; Mr. O. E. Coope, M.P., in the chair. After the transaction of the ordinary business, it was resolved, on the motion of Dr. Glover, seconded by Mr. J. Boodle, to ask the Lord Mayor to attend, as heretofore, at St. Paul's and Westminster Abbey on Hospital Sunday. It was then resolved, on the motion of the Rev. Mr. Rowse, seconded by Professor Marks, to solicit the Lord Mayor to write to the leading journals a day or two before Hospital Sunday, pleading the cause. It was next resolved that the clergy and ministers of the Abbey, cathedrals, churches, and other

places of worship in the metropolis be earnestly requested to allow all the services performed on June 30th to be made available for the general collection on behalf of the Fund, and that the resolution be advertised.

#### SMALL-POX IN LONDON.

AT the usual fortnightly meeting of the Metropolitan Asylums District Board to-day, the return of the small-pox hospitals showed that there were 562 patients remaining, against 677 at the end of the previous fortnight, being a decrease of 115. In the same period, the number of fever-patients at Stockwell and Homerton was 253, against 252 in the previous fortnight, showing an increase of one patient. Lieutenant-General Sir H. P. De Bathe was appointed a member of the Training-ship Committee until the 25th of March next.

#### THE VIOLET POWDER POISONING CASE.

AT the last meeting of the Edmonton Local Board of Health, Dr. Reid, the medical officer, reported as follows. "The solicitors to the Treasury have communicated with me on the subject of my previous report as to cases of poisoning in Edmonton by arsenic being mixed with violet powder, and, in the presence of Mr. Roots of the Criminal Investigation Department, Scotland Yard, several packages of violet powder have been more fully tested in my surgery. In one package, I should think arsenic was found in large quantities enough to warrant the suspicion of its constituting half, if not more, of this compound sold as violet powder, and this packet also bore the name of King. I have tested packets purchased at the various chemists' shops at Edmonton, and found the violet powder therein to be pure starch and the ordinary constituents of scented violet powder. During the past fourteen days, I have not seen any fresh cases of poisoning due to violet powder, and the other cases are progressing favourably."

#### RECIPROCITY OF MEDICAL PRIVILEGES.

M. MARVAISE has reintroduced into the French Assembly the Bill which proposes to prohibit foreign physicians from practising in France, except after passing two examinations conducted in the French language—one upon the science and the other upon the clinical practice of medicine. At present, it is almost impossible for any English physician to obtain permission to practise in France. The Medical Acts Amendment Bill of the Duke of Richmond is far more liberal, since it proposes that a duly qualified foreign or colonial medical man of ten years' standing, and of good character, shall be entitled to registration in the United Kingdom *without examination* at all on payment of the registration fee.

#### THE PUBLIC HEALTH.

THERE were 2,120 births and 1,300 deaths registered in London last week. Allowing for increase of population, the births were 195, and the deaths 40, below the average numbers in the corresponding week of the last ten years. The annual death-rate from all causes, which in the three previous weeks had been equal to 20.1, 20.7, and 21.6 per 1,000, declined to 19.1. The deaths from small-pox, which had been 40 and 42 in the two preceding weeks, declined to 24 last week; and were fewer than in any week since the middle of November last. Of these 24 fatal cases, 9 were certified as unvaccinated and 7 as vaccinated; in the remaining 8 cases (of which 7 occurred in private practice) the certifying medical practitioners omitted to give any information as to vaccination. The number of small-pox patients in the Metropolitan Asylum Hospitals, which was 854 on the 20th of April last, has since steadily declined to 529 on Saturday last; the number of new cases admitted to these hospitals, which had been 170, 126, 108, and 84, in the four preceding weeks, rose again to 100 last week. The deaths referred to disease of the respiratory organs, which had steadily increased from 199 to 270 in the four preceding weeks, declined again to 200 last week, but exceeded the corrected weekly average number by 6; 121 resulted from bronchitis, and 54 from pneumonia. There were 20 deaths from measles, 24 from scarlet

fever, 8 from diphtheria, 101 from whooping-cough, 22 from different forms of fever, and 21 from diarrhoea. In the Greater London, 2,606 births and 1,534 deaths were registered, equal to annual rates of 30.6 and 18.0 per 1,000 of the population. In the Outer Ring, two fatal cases of small-pox were registered in West Ham, 1 in Stratford, and 1 in Bromley registration sub-districts. The mean temperature was 55.7 deg., and 2.8 deg. below the average. The coldest day was Saturday, when the mean was only 51.6 deg., and was 7.4 deg. below the average. Rain fell on six days of the week, to the aggregate amount of 1.28 inches. The duration of registered sunshine in the week was 39.8 hours, the sun being above the horizon during 115.4 hours. The recorded duration of sunshine was, therefore, equal to 34 per cent. of its possible duration.

#### PROFESSIONAL CONFIDENCES.

A LAW protecting physicians from the violation of professional confidences in courts of law has been adopted by many of the States of America. A Philadelphia correspondent of the *Boston Medical Journal* reports that, its wisdom having now been tested by an experience of fifty years in the neighbouring State of New York, the medical societies of the former city have been induced to move in the matter. A concurrent resolution was passed recently by the Philadelphia County Medical Society, the College of Physicians, and the Obstetrical Society, petitioning the legislature for the passage of an Act providing that "no person duly authorised to practise physic or surgery shall be allowed or compelled to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician or to do any act for him as a surgeon". This Act has been duly presented and referred.

#### THE CONTAGIOUSNESS OF DIPHTHERIA.

THE Massachusetts Board of Health has been studying this subject in connection with recent outbreaks in the State. Dr. Bowditch, in the course of a recent discussion reported in the *Boston Medical Journal*, stated that he could not speak for the State Board of Health; but for himself he had formed decided opinions, especially since studying an epidemic of diphtheria during the past summer at a town adjacent to Vergennes, Vermont. He felt that the course of that epidemic went strongly to support the following views. 1. Diphtheria is *contagious*: numerous instances seem to be accounted for only on that idea. 2. That it is *infectious*, seems strongly indicated by the fate of one family, all the members of which except the father were kept away from the sick persons and houses in which they were lying. The family took every precaution, and seemed for a time successful, when their neighbours were fatally attacked. The father, however, as a neighbourly act, laid out one dead body and attended some funerals, returning home every night. After the disease had apparently subsided, his three children and wife were suddenly seized. The wife was paralysed about the palate, and the children died. 3. Filth appeared to have its effect in making the disease more virulent and destructive. An example, apparently, of this fact was the following, which took place in what, at first glance, seemed a nicely situated and admirably built house. It was the only brick house of those parts; it stood in a broad open field; it had a granite foundation raising it from the ground, while the others were of wood, and resting, as most of our farm-houses do, almost, if not quite, upon the level of the greensward around them. It had, Dr. Bowditch learned, a firmly cemented cellar. Moreover, a drain led from the house, in order to avoid the unsightly appearance of the slops when thrown upon the ground around the house, which custom was universal here save at this house. The drain was untrapped, and ran by a very slight descent into a bog about three hundred feet distant. Its mouth for the reception of slops was close to and directly in front of the kitchen-door; its other opening terminated in the bog of mud and water, in which the cattle stood to cool themselves in the summer, and dropped urine and faecal matter, while their

feet stirred up the mud and these new materials. The wind could enter this opening, carrying the malaria of the bog, the fecor of urine and faecal matter. These, combined with that from the slops, would be easily driven directly into the kitchen-door. In this family, the mother and three children were killed very rapidly. 4. Clearliness seemed to ameliorate the disease, as shown in another house. This was situated on the summit of a dry hill overlooking the whole horizon. The slops, it is true, were thrown from a side porch upon the ground; but they ran rapidly down the slope. Everything about the house was extremely neat. No contaminated air could easily find access to the homestead. One child had undoubted diphtheria, and the rest had mild sore throats. All recovered. Dr. Bowditch could not help thinking that, if the children and mother in the former case had been in a similar situation, it is possible that they too would have escaped death. In conclusion, Dr. Bowditch said that, in his opinion, we ought to consider the disease as contagious and infectious, and govern ourselves accordingly. Physicians should be careful to visit no such cases before seeing other delicate patients—puerperal cases, for example. We should act as we do when called to see a case of erysipelas and a puerperal case the same day, under which latter circumstances we might bring death to the puerperal women if we were not very cautious about our hands and clothing in going from one to the other.

#### A METROPOLITAN PROVIDENT HOSPITAL.

A VERY important experiment is about being tried in the metropolis, by opening a provident hospital in Battersea Parish, on the verge of Wandsworth Common. Our readers may remember that, about four years ago, the old free dispensary in Battersea was converted into a provident dispensary. The success of this dispensary has led to a demand for an institution where in-patient treatment can be obtained in a somewhat similar manner. In order to meet this want, the Vicar of Battersea, Canon Erskine Clarke, has secured Bolingbroke House, Wandsworth Common, and it will shortly be opened as a provident hospital. As a rule, no one will be admitted without payment, except in the case of accidents; these will be received at any time, on the authority of the medical officers. No letters of admission will be issued. Patients will be admitted in the order of their selection by the staff; but a preference will be given to those who have been for at least six months *members of any provident dispensary*. For such persons, as well as for the servants of governors, a charge will be made of 2s. 6d. a night. Other persons will only be admitted if there be vacancies, and upon terms which shall be specially arranged. We understand that Canon Erskine Clarke and those who are co-operating with him are anxious to start this hospital upon the lines which are deemed the wisest and best by those who have paid special attention to the subject. As far as we can judge by the prospectus and provisional rules, the proposed institution seems likely to meet a want which has often been expressed, and also to set an useful example to some of our older medical charities.

#### SMALL-POX AND VACCINATION.

BETWEEN the end of May 1876 and February 1877, there were 1,001 cases of small-pox admitted into the Hospital for Infectious Diseases at Mill Road, Liverpool. There were 158 deaths, or 15.5 per cent., of the total number of cases admitted; and of these, 45 deaths, or 6.2 per cent., occurred amongst vaccinated persons; 100, or 45.9 per cent., amongst the unvaccinated; and 13, or 18.1 per cent., among those who had no marks on their arms, but who were reported to have been vaccinated. Dr. Taylor, the Medical Officer of Health, says that, assuming that 4 per cent. of his population were unvaccinated, which is the proportion calculated by Dr. Seaton to be unvaccinated amongst the English population, there would be 21,083 unvaccinated and 506,000 vaccinated persons in Liverpool; and, consequently, 14.4 per 10,000 of the vaccinated population were sent to the hospital, and there were 0.9 deaths per 10,000 amongst them. On the other hand, there were, on this calculation,

lation, 103.4 cases per 10,000 unvaccinated persons sent to the hospital, or about seven times the proportion amongst the vaccinated, and 47.4 deaths per 10,000, which is more than fifty times the mortality amongst the vaccinated. Dr. Taylor is further of opinion that there were probably four times as many cases in the borough as were sent to the hospital; and if so, out "of every 10,000 vaccinated persons, 57.7 had the disease, and 3.6 died; and of every 10,000 unvaccinated persons, 413.6 had the disease, and 189.7 died". In the Homerton Hospital, the statistics were nearly as unfavourable for the unvaccinated, as Dr. Collie says they died at the rate of 53 per cent. on the admitted cases; whilst the tables show that those on whom there were no marks, or who were said to have been vaccinated, gave a mortality of 37.5; the badly vaccinated, 23.5 per cent.; and the fairly vaccinated only 2.3 per cent. Dr. Taylor also states that, out of 5,733 cases admitted in 1871-77, the mortality was as follows, viz., only 3.57 per cent. amongst those having good marks; 11.40 per cent. of those having imperfect marks; 28.98 per cent. of those said to have been vaccinated, but without marks; and 46.17 per cent. of those who were confessedly unvaccinated. The mortality amongst the confessedly unvaccinated at Liverpool and at Homerton, viz., 45.9 and 46.17 per cent. respectively, differs so little as to show that, during an epidemic, this rate may fairly be considered as normal, whilst the well-vaccinated should not give a mortality of above 4 per cent. of the total attacks. When the comparative immunity against an attack is taken into account, it seems incredible that any one can argue against the efficacy of efficient vaccination.

#### IS THE MOSQUITO THE INTERMEDIARY HOST OF THE FILARIA SANGUINIS HOMINIS?

DR. T. R. LEWIS, who first called attention, about five years ago, to the blood of certain persons in India being infected by minute nematoid parasites—the *Filaria sanguinis hominis*—has recently published some further observations on the subject in the *Proceedings of the Asiatic Society of Bengal*. In the autumn of last year, Dr. Patrick Manson made the interesting discovery that embryo hæmatozoa may be found in the stomachs of mosquitoes that had been feeding on the bodies of persons in whose blood these parasites exist; and it has since been alleged that the mosquito is the intermediary host of the *Filaria sanguinis hominis*, and that residence in this insect is necessary for the completion of the life-cycle of the filaria. Dr. Lewis has, therefore, been making experimental observations to ascertain how far this allegation is correct—whether it is the fact that the filaria do undergo undoubted developmental changes in the stomach of the mosquito. It is the more important to determine this point with accuracy, as, from the association of filarious blood with some elephantoid forms of disease, this very common insect, the *Culex mosquito*, may act as a disseminator of the blood-parasites in man and the diseased conditions with which they have been observed to be associated. The results of Dr. Lewis's first observations served to throw considerable doubt on the alleged fact that the mosquito serves as the intermediary host to the development of the *Filaria sanguinis hominis* or any other nematoid hæmatozoon; but his later examinations have rather tended to confirm it. The earlier observations were made by removing the alimentary canal with its contents from the other tissues of the insects; and so long as the examinations were thus conducted separately, so long it was found that the hæmatozoa, when present, according to the length of time the insect had been kept before the examination was made, succumbed to the digestive action of the insect's stomach. After the third or fourth day, Dr. Lewis saw no active specimens of these entozoa in the stomach or in any part of the alimentary canal of the mosquito; and, after the fourth or fifth day, it was very rare for any traces of hæmatozoa-like objects to be detected at all. Subsequently, however, the examinations were made under different conditions; and then it was shown that, although the stomach digests a great number of the ingested hæmatozoa, as just mentioned, "others actually perforate the walls of the insect's stomach, pass out, and then undergo developmental stages in its thoracic and abdominal tissues". Dr. Lewis

finally concludes thus: "With regard, however, to the inference that the mosquito is the particular intermediary host of nematoid hæmatozoa, it cannot be said that even these later observations are sufficiently conclusive to warrant a positive statement being made at present; for though, assuming that of the various parasitic forms which have been seen several are actually transitional stages in the development of one and the same entozoon, it is to be noted that even the most advanced stage hitherto observed is still a very immature one—no trace of reproductive organs, for example, being distinguishable; and every attempt hitherto made by myself to obtain a more advanced condition has proved unsuccessful. Further observation, however, may overcome or explain this want of success."

## SCOTLAND.

OPERATIONS have commenced for the introduction of water into the village of Kilmalcolm.

A DOMESTIC servant named Webster committed suicide at Letty Crewstee, a village near Aberdeen, on Sunday last, by swallowing a quantity of oxalic acid. No reason is assigned for the act.

AN epidemic of typhoid fever has broken out in the town of Galashiels, in the Hailburton district. Upwards of forty cases have been reported. It is suspected that the water may have been the cause of the outbreak, and samples have been forwarded for analysis.

TYPHUS fever is reported to be spreading to a serious extent in Aberdeen, and has almost assumed the dimensions of an epidemic. On Sunday last, four members of one family were taken to the Infirmary, where there were at that date altogether twenty patients under treatment.

#### THE COLQUHOUN BEQUEST FOR INCURABLES.

THIS Glasgow Charity relieved last year one hundred and twenty-two persons, the amount allowed to each varying from £3 5s. to £13 *per annum*. The total revenue reached £875 last year. Mr. Colquhoun's trust-deed contemplated the further development of the charity, by the addition to its capital funds of donations or legacies from those who approved of its objects.

#### ALLEGED ILLEGAL DETENTION OF A LUNATIC.

A CASE was tried in the Court of Session, last week, in which a man named James Gallagher, at present an inmate of the District Asylum at Larbert, and the Inspector of Poor in the parish of Campsie, are pursuers, and the Procurator Fiscal of Stirling is defender, the object being to obtain the release of Gallagher. Gallagher was at one time a labourer on the estate of Glorat, which belongs to Sir Charles Stirling. He declared that he was on one occasion ill-treated by Sir Charles and his gamekeeper; he thereupon wrote several threatening letters to Sir Charles, who complained to the Procurator Fiscal, on whose initiative Gallagher was sent to the asylum. He was subsequently liberated by his father taking his name from the poor-roll. For a time, he left the district and conducted himself well; but recently he returned to Glorat, and again commenced writing threatening letters to Sir Charles Stirling, among other things threatening to blow up Glorat House with dynamite. He was accordingly brought before the Sheriff in March last, when he was sent back to the asylum. He was examined there by three medical men, who all certified him to be insane. It appeared that he laboured under a delusion, which had coloured his life for the last six years and led to fits of excitement. The particular delusions under which he lay were that, for some injury, real or imagined, he had money claims against Sir Charles for many thousands of pounds; that Sir Charles had forfeited his estates, which Gallagher anticipated Her Majesty the Queen would hand over to him; that forty-seven persons whom he named had conspired together to injure him, and to prevent his getting justice; and that, if the law refused his petition, he was entitled to put dynamite

under Glorat House and blow up it and its inmates. There were other symptoms of insanity mentioned in the certificates. After hearing counsel, the Court reserved judgment. Judgment was subsequently given against the lunatic.

#### DISPOSAL OF GLASGOW SEWAGE.

A COMMITTEE of Glasgow Town Council met, last week, to consider the best means of disposing of the city sewage. It was agreed to recommend to the Council that the sewage should be carried to Dalmuir, about seven miles below Glasgow, where it will undergo a process of filtration before it is allowed to enter the river. The sewage will be intercepted at a certain point in the city, and carried to Dalmuir in a sewer, which will have to be constructed for the purpose. If the Council approve of the scheme, it is more than probable that operations will at once be begun to carry it into effect, as a considerable portion of the ground in the neighbourhood of Dalmuir is already the property of the Corporation of Glasgow. This is in part the scheme of Sir John Hawkshaw, although his proposal was of a more extensive nature, and the point at which the sewage was to enter the Clyde was more distant from the city, Sir John proposing that it should be carried to the Ayrshire coast. It is anticipated that the proposal of the Committee will meet with considerable opposition.

#### HEALTH OF GLASGOW.

DR. J. B. RUSSELL of Glasgow has just issued his annual statement, giving a return of the deaths in the city during the past year. The population within the municipal boundary is estimated at 546,921, giving a percentage of 91 persons to the acre. In the Brownfield division of the city, the number of persons to the acre is 505; while Monteith Row has only 31. In one district of the city, the death-rate has exceeded that of the births. The total number of deaths from all causes was 13,758, among these being 1,974 persons aged 60 and upwards. These figures give a death-rate of 25.16 per 1,000 of population. In a table dealing with the causes of deaths, it appears that acute diseases of the lungs proved fatal to 3,555 cases, consumption coming next with 1,730. Sixty-two persons died of typhus and 181 of enteric fever. The total number of deaths of persons in Friendly Societies was 5,223, of whom 595 were infants under the age of one year. In one district, that of Bridgegate and the Wynds, the percentage of illegitimate births reached the high figure of 20.20. In Springburn and Maryhill district, it was only 3.40.

## IRELAND.

DR. LEWIS MANSERGH RAWSON, medical officer of Baltinglass, Balyore, and Strangford Dispensary District, died at Baltinglass on the 11th instant.

DR. NEALE, medical officer of Clonaslee Dispensary District, met with a severe accident last week. He was thrown violently from his horse, and besides other injuries received a fracture of the left arm.

MR. WRIGLEY GRIMSHAW died at Bray on the 16th instant, at an advanced age. Mr. Grimshaw was a Fellow of the Royal College of Surgeons in Ireland, and formerly practised in Dublin.

At a recent meeting of the Brosna Dispensary Committee, Tralee Union, Dr. O'Sullivan was elected medical officer to No. 1 division of the district, at a salary of £100 *per annum*, with registration and vaccination fees.

THE King and Queen's College of Physicians and the Royal College of Surgeons in Ireland have sent deputations to London to watch the progress of the various Medical Bills, now before the House of Commons, and to bring the views of their respective Colleges under the notice of the honourable members in charge of the Bills.

#### HEALTH OF DUBLIN.

WE are glad to note an improvement in the death-rate of this city. The deaths registered during the week ending Saturday last represent an annual mortality of 25.8 per 1,000. The mortality from zymotic diseases has fluctuated for some weeks past; but in each, owing to cases of small-pox and whooping-cough, it has been much over the average for the corresponding period in the ten years 1868-77. Last week, 37 deaths from diseases of this class were registered; being 22 less than in the preceding week, but 14 over the average for the twenty-fourth week. The deaths from small-pox are one less than in the week ended 8th instant. The hospital returns show that 97 small-pox patients were admitted during the week (being 11 more than in the preceding week), 59 were discharged, 14 died, and 258 remained under treatment on Saturday.

#### CONG DISPENSARY: CHARGE AGAINST DR. MCGUIRE.

At a recent meeting of the Guardians, a communication was received from the Local Government Board in reference to a charge brought against Dr. McGuire by the parish priest for neglect of his duties, in which the Board considered that Dr. McGuire was not free from blame, and cautioned him in future to be more careful, or they would take more serious notice of his neglect than on the present occasion. The Guardians, however, appear to be perfectly satisfied with their medical officer, and passed a resolution, with but one dissentient, expressing their thorough approval of the way in which Dr. McGuire on all occasions attended to his arduous dispensary duties; but, nevertheless, in deference to the Local Government Board, requested him to be more particular in future.

#### PAYMENT OF MEDICAL SUBSTITUTES.

THE following resolution was unanimously adopted at a recent meeting of the Guardians of Dundalk Union: "That each dispensary medical officer in connection with this Union shall pay, out of his resources, the fees charged by a duly qualified medical man who may act as *locum tenens* or substitute for said medical officer, save and except that said dispensary medical officer is then labouring under a disease caught in the discharge of his professional duties."

#### LUNATIC ASYLUMS, IRELAND: ANNUAL REPORT.

FROM the twenty-seventh report of the District, Criminal, and Private Lunatic Asylums in Ireland, which has been recently issued, we learn that, on the 31st of last December, there were 12,380 lunatics in these institutions, of whom 3,372 were located in poor-houses, 8,183 in district asylums, and 636 in private asylums. There was an increase in the accommodated insane during the past year of 257, as compared with 1876; whilst regarding the existing census of Ireland as 5,412,000, it would appear that the insane are in the ratio of 1 to 420 in the general population. An important element of consideration in reference to the prevalence of mental affections must not, however, be forgotten; namely, the reputed insane at large, who, from recent returns, amount to 6,626, being composed of 986 lunatics proper, 4,408 idiots and imbeciles, and 1,232 epileptics. At the end of 1876, there were 8,073 patients in district asylums, and last year 2,134 were admitted, or a total of 10,387 under treatment during the past twelve months. Of these, 1,076 were discharged cured and 249 improved, constituting between both categories a total of 1,325, or a percentage of good results on admissions of 57, which is regarded as satisfactory. Forty-nine cases were removed from the district asylums tranquil, but incurable. The deaths during the year came to 821, all from natural causes, except one which was suicidal. Estimated on the total number under treatment, the mortality would be 8 per cent.; the greatest death-rate—almost double that elsewhere—being in the Cork and Dublin asylums, which contained a very large proportion of physically infirm and aged inmates. The admissions were 2,314 during the year, 1,924 being cases of a first attack, and 390 relapses, against 2,344 in the previous year; so that the Commissioners consider that lunacy is not so progressive in Ireland as in other parts of the United Kingdom.

We find that though, in the population, females are in excess by nearly  $2\frac{1}{2}$  per cent., this number in lunatic asylums is 8 per cent. less than that of males; also that there is a marked disparity existing between the married and unmarried inmates of Irish asylums, public as well as private; the married and widowed, according to the present returns, amounting between both sexes to only 2,355, the single to 5,491. This discrepancy is totally at variance with what is elsewhere recognised; and if lunacy were a malady of early life, or one prior to puberty, or if marriage in Ireland were an institution of advanced life, some explanation might be available; but facts are the reverse. Intemperance and irregularity of life were referable to 693 cases in district asylums, but it is difficult to say how many can be absolutely attributed to drunkenness; forasmuch as dissipation and a continued indulgence in alcoholic drinks run close'y into one another as cause and effect, both leading from vice to crime. The report speaks favourably of the general condition of the public asylums, but regret is expressed at the unsatisfactory condition of Londonderry district in respect to its insane poor, one not very creditable to so flourishing a locality. The asylum there, built for 112 patients, contains at present 260; and so overcrowded is it, that eight or nine beds are to be found in dormitories scarcely intended for five; whilst there is an absence of an infirmary, chapel, and suitable out-offices. In conclusion, the inspectors observe that, if the utility of public lunatic institutions be estimated by results, the district asylums of Ireland, tested by the number of cures effected in them, by their average low mortality, by their immunity from the recurrence of fatal or serious accidents—one solitary suicide being the only untoward occurrence that took place during the year, in a population of over ten thousand inmates, a large portion of whom were admitted as dangerous,—may fairly compete with the best regulated of kindred establishments in other countries.

#### CLINICAL INSTRUCTION AT THE BELFAST WORKHOUSE HOSPITALS.

At a meeting of the Belfast Board of Guardians, last week, the admission of medical students to the Union Hospitals for clinical instruction was under consideration. Resolutions in reference to this matter having been adopted by the Board last December on the subject of the proposed arrangements, and forwarded to Dublin Castle, last week the guardians received a communication from Dublin, informing them that the Lords Justices, in compliance with the request contained in their last resolution, have inquired why the students in question have not been permitted to avail themselves of the very valuable information, which would be afforded them of receiving extensive clinical instruction in the medical and surgical wards of the Belfast Workhouse; and learn with regret that the proposal has not been carried into effect, in consequence of the refusal of the Royal Hospital to accept the terms on which the College and the medical officers of the Union considered that an amalgamation might be effected. Dr. Corry, one of the guardians, thought it would be more convenient for students attending at the Queen's College to visit the Workhouse than go to the Royal Hospital, and proposed a resolution to the effect, that the clerk should communicate with the Queen's University in Ireland, and other licensing bodies, requesting them to recognise the certificates of attendance at the infirmary and hospital of the Belfast Union Workhouse, which was adopted unanimously. It is stated that the medical officers of the infirmary and hospital would have extra duties to perform, and therefore requested a portion of the fees paid by the students to the Belfast Royal Hospital should be given them, an arrangement which was objected to by the medical staff of that institution.

#### DUBLIN SANITARY ASSOCIATION.

THE annual meeting of this useful Association was held on the 13th instant, Lord James Butler in the chair. In alluding to the existence of small-pox in Dublin, the report of the Executive Committee pointed out that, besides neglected vaccination, there are unfortunately other causes for the prevalence of small-pox, which do not require any new enactment for their removal. These are the disgraceful sanitary state

of the city, as evinced by the high death-rate; the want of proper sanitary organisation and supervision; the want of proper means of removing infected persons to hospital; and the want of epidemic hospital accommodation. The latter is a great defect in hospital organisation in Dublin. The report also referred to the ineffectual efforts made by the Association to induce the Government to institute an inquiry into the cause of the great mortality in Dublin, and to other important sanitary matters. The adoption of the report was moved by Mr. C. H. Meldon, M.P., who described the sanitary state of Dublin as being about as bad as bad could be; its mortality exceeding that of any other city in the kingdom.

#### THE MEDICAL ACT (1858) AMENDMENT BILL.

THE following observations on the Medical Act (1858) Amendment Bill, as passed by the House of Lords, and now standing for second reading in the House of Commons, have been prepared and circulated by the Council of the Irish Medical Association.

The Council of the Irish Medical Association view with satisfaction any attempt at legislation which may tend to improve medical education and medical examinations, and to remove the present unsatisfactory state of the qualifications which entitle their holders to admission to the *Medical Register*. The Council do not think that the present Bill can be considered as sufficiently fulfilling the above objects, for the following reasons.

1. That the constitution of the General Medical Council is not affected by the Bill; the General Medical Council, as at present constituted, only directly represents the Government and the corporations, but scarcely at all the great body of the medical profession. That, while it is owing to the failure of the corporations to adopt conjoint examinations, and the omission of the General Medical Council to enforce uniformity of education and examination, that the proposed legislation has become necessary, yet the regulation of examinations—owing to the absence of direct representation of the members of the profession—is to be almost altogether vested in the representatives of the licensing bodies. The Council of the Irish Medical Association consider that the Bill should provide for the direct representation of the great body of the profession in the General Medical Council, each division of the United Kingdom being duly and separately represented.

2. That the Bill, by providing for admission of persons to the *Medical Register* who have obtained only a qualifying certificate of proficiency in medicine, surgery, and midwifery from the conjoint medical examining board, without having a diploma from any of the existing licensing authorities, must inevitably tend to the gradual extinction of the medical corporations, and eventually, as a consequence thereof, also to the extinction of the conjoint medical examining board itself.

3. The Council are most decidedly of opinion that any measure which threatens the extinction of the Colleges, or even curtails their usefulness, would be most seriously detrimental to the interests of the profession and the public.

Lastly, there are some minor defects in the Bill which the Council believe require amendment; they therefore beg to make the following observations upon the Clauses of the Bill.

Clauses 5, 6, and 7 provide for the registration of certain colonial and foreign qualifications. This appears to be a valuable and just provision, provided it be reciprocated by the colonial and foreign governments.

Clause 2 provides for the erasure from the *Register* of the names of persons guilty of felony or misdemeanour, or of any infamous or disgraceful professional conduct. This clause is approved, but at the end a provision is introduced which exempts from its operation a person who has been guilty of an offence, trivial in its nature, or committed under excusable circumstances. The Council think all such exceptions should be omitted.

Clause 13 makes it incumbent upon the General Medical Council to make rules for the examinations. The Council approve of the sub-clauses, except 2, "which provides that the examination rules shall not require a candidate to adopt, or refrain from adopting, the practice of any particular theory of medicine or surgery". It is manifest that this subclause would give the candidate power to answer questions according to his own views, and obtain credit therefor, quite independently of the opinion of the examiners as to the correctness of the answer.

With reference to the admission of women to the medical profession, the Council, without expressing any opinion as to the advisability thereof, are distinctly of opinion that, if admitted, they should comply with the same conditions as are required of men.

Clause 21 makes more effectual provision against quacks, but does not prohibit the practice of unqualified persons; the Council think that practice for gain by unregistered persons, whether they assume professional titles or not, should be made penal, and desire to point out that in Ireland no such provision as the English Apothecaries' Act exists to prevent unqualified persons from practising for gain. This clause also deprives private persons of their privilege to prosecute unregistered persons, and only makes it permissive for the Medical Council or the corporations to prosecute. There does not seem to be any reason why private persons should be deprived of their present right in this matter.

Clause 22 provides for the examination and registration of dentists. This clause is very objectionable, and contrary to the principle of the Bill, which requires a qualification in medicine and in surgery to admit to general practice; but this clause would permit a person who is not a surgeon, or not in possession of any existing dental diploma, or any qualification whatever, to practise dental surgery, and to be registered as a legally recognised dental practitioner.

Clause 23 provides for the examination and registration of midwives. This is, no doubt, a much required and useful measure; but the Sub-clause 5, which provides for the appointment of local examinations and local registers, is most objectionable; it even provides that local bodies, like town councils, may become the controlling authority in such matters. The licensing of midwives should be confined to properly constituted medical bodies.

Clause 25 permits the General Medical Council to delegate to certain bodies or persons the duty of framing examination rules, which the Council cannot approve, because it would almost certainly tend to frustrate one of the chief objects of the Bill, viz., uniformity of examination.

THOMAS PURCELL, Chairman of Council.

JOHN WILLIAM MOORE, Honorary Secretary to Council.

#### BRITISH MEDICAL ASSOCIATION: JOINT COMMITTEE ON STATE MEDICINE.

ON Tuesday last, a meeting of the Joint Committee of the British Medical and Social Science Associations on State Medicine and the Administration of the Sanitary Laws was held at the rooms of the latter Association, in the Adelphi; Dr. SHRIMPTON in the Chair. There were present: Mr. Clode, Dr. Corfield, Mr. Ernest Hart, Mr. Baldwin Latham, Mr. John Liddle, Mr. Neison, Dr. Stewart, and Dr. Tyacke. It was reported that, in consequence of the withdrawal of the County Administration Bill by the Government, the presentation of the memorial to the Local Government Board, agreed to at the last meeting of the Committee, was postponed till an early date next session, and, in the meantime, a copy was ordered to be forwarded to Mr. Slater-Booth, with a request that he would give it consideration.

It was resolved, on the motion of Mr. HART, seconded by Dr. TYACKE: "That an inquiry be addressed to the extra-metropolitan medical officers of health, asking (1) whether they report periodically as to the sanitary condition of their districts; (2) if so, how often and in what form; (3) whether such reports are printed, and, if so, whether circulated, and the number published; and asking also for a copy of the last report. That Dr. Stewart, Mr. Michael, Mr. Clode, Mr. Hart, and Mr. Liddle be appointed a subcommittee to report on the answers received."

The draft memorial to the Duke of Richmond, Lord President of the Council, in reference to the institution of a State Medicine qualification, was considered. Communications, agreeing with the memorial, were read from Mr. Michael, Dr. Ransome of Manchester, Dr. Wilson of Cheltenham, Dr. Bond of Gloucester, and Mr. Haviland of Northampton. The memorial, as amended, was agreed to in the following form.

*"To the Right Hon. the Duke of Richmond and Gordon, Lord President of the Council.*

"The Memorial of the Joint Committee on State Medicine of the British Medical Association and the National Association for the Promotion of Social Science humbly sheweth:

"That it is desirable that opportunities should be given for medical men to obtain registrable qualifications for the performance of certain public duties included under the head of State Medicine.

"That State Medicine differs greatly in its aim from curative medical practice, and involves a special knowledge of certain departments of medical science, such as are needed for the maintenance of a high standard of public health, and for promoting the physical improvement and effective strength of the general population.

"That, under the Public Health Act of 1875, medical officers of

health have been appointed by every local authority throughout the kingdom; but that, at the present time, there exists no recognised law for testing the fitness of candidates for such appointments.

"That, so long ago as the year 1869, the General Medical Council reported in favour of providing a registrable qualification in State Medicine in any amended Bill that might thereafter be prepared for Parliament.

"That, during the last six years, evidence in favour of such a measure has been brought forward in three successive reports by a committee appointed by the British Medical Association to consider the subject of a State Medicine qualification, and such reports have been ratified by the Association.

"That your memorialists, therefore, respectfully beg to recommend that, in the Bill for the Amendment of the Medical Act now before Parliament, clauses shall be inserted providing that the conjoint boards established by that Bill shall examine candidates in the subject of State Medicine, and shall grant certificates of competency, which shall be registrable as qualifications in State Medicine for medical appointments in the public health service. Candidates for examination to be persons who shall be registered under the Medical Act, and who shall have gone through such further courses of study and practical instruction, and attained to such age, as the General Medical Council may require."

Copies of the memorial, as amended, were ordered to be forwarded to the Duke of Richmond and Gordon, Mr. Secretary Cross, Mr. Slater-Booth, and Dr. Acland, President of the General Medical Council; and Dr. Stewart, Dr. Tyacke, Dr. Corfield, and Mr. Hart were appointed a subcommittee to confer with ministers and others as to the best means of carrying out the wishes of the Committee in respect to the memorial.

#### THE HARVEY TERCENTENARY MEMORIAL FUND.

A GENERAL meeting of the subscribers to this fund was held, by permission of the President of the Royal College of Physicians, at the College, on Tuesday, the 18th instant. There were present: Dr. J. Risdon Bennett, the President of the College; Sir George Burrows, Bart.; Mr. Prescott Hewett; Dr. F. J. Farre; Mr. John Fitness (Mayor of Folkestone); Dr. Quain; Dr. Owen Rees; Mr. John Simon, C.B.; Dr. C. J. Hare; Dr. J. G. Glover; Dr. Fincham; Mr. Edwin Saunders; Mr. Allingham; Dr. Bagley; Dr. Norman Kerr; Mr. S. Eastes; Mr. Rushforth; Mr. Daughish; Mr. J. S. Eastes, jun.; Dr. W. H. Haden, etc., and Mr. W. G. S. Harrison and Mr. George Eastes, the Honorary Secretaries. Letters were received from Lord Derby and other subscribers, regretting their inability to be present. Dr. R. Bennett, the President of the College, took the chair.

Mr. G. EASTES, the London Honorary Secretary, read the report of the London Executive Committee, which stated that, early in the present London season, the Committee decided to make an appeal for further funds. An appeal was accordingly sent to various medical corporations and societies, and to the branches of the British Medical Association. The result had been the addition of a sum exceeding £400 to the subscription-list. Another appeal had been made to all classes of the community, which, together with a sum of £30 produced at a lecture generously given at Folkestone, on April 1st, by the Rev. R. C. Jenkins, Rector of Lymington, on "Harvey and his Claims as a Discoverer", had brought in a further addition of £350 since March last. Altogether, a gross sum of £1,680 had been contributed, of which £1,388 had been received. Subscriptions were still coming in, and the Committee felt that they were now quite justified in advising the subscribers to take steps for the selection of a sculptor to whom the execution of the memorial statue might be entrusted.

The report of the auditors (Dr. C. J. Hare and Dr. J. G. Glover) was read by the former. It stated that the necessary expenses had been £160; and that there was, therefore, in hand at the present time a balance of £1,220—of which £700 were invested in Exchequer Bills, bearing interest, whilst the balance was placed to the credit of the Fund at the Western Branch of the Bank of England. The report also spoke favourably of the accuracy with which the accounts had been kept. The two reports were received.

It was proposed by Sir G. BURROWS, and seconded by Dr. C. J. HARE: "That a subcommittee be appointed, for the purpose of selecting an artist to whom the making of the memorial statue shall be entrusted; and that Mr. E. H. Lushington, Dr. Quain, Mr. Prescott Hewett, Mr. John Simon, Dr. Owen Rees, Mr. J. J. Lonsdale (Recorder of Folkestone), Mr. J. Fitness (Mayor of Folkestone), Mr. W. Bateman, and the Honorary Secretaries (Mr. W. G. S. Harrison and Mr. George Eastes) form the subcommittee; five to be a quorum." Mr. John Simon and Dr. Hare proposed that the name of Sir G. Burrows

should be added to the list of the subcommittee. The two propositions were put together, and carried unanimously.

The Honorary Secretary stated that he had received the following letter from Lord Derby, dated—

"Knowsley, Prescott, June 17th, 1878.

"Sir,—As far as I am able to judge, I entirely approve the steps you are taking in the Harvey Memorial. But I must ask to be excused from serving on the subcommittee which is to be formed. I shall be but little in London during the present year, and should not be able to give effective assistance.

"I remain, your obedient servant, "DERBY."

It was proposed by Mr. EDWIN SAUNDERS, seconded by Dr. FINCHAM, and resolved: "That the subcommittee have full powers to select and arrange with a sculptor in any way that they may think proper; whether by open competition, or by inviting three or four well-known sculptors to send in designs, with a view to the selection of the best; or by the selection of an artist without such competition."

It was proposed by Dr. QUAIN, seconded by Dr. OWEN REES, and resolved: "That the present London and Folkestone Executive Committees be requested to act again in all particulars (except in the selection of, and contracting with, the sculptor) on behalf of the subscribers to the Memorial Fund."

It was proposed by Dr. BEGLEY, seconded by Sir G. BURROWS, and resolved: "That a vote of thanks be given to the Right Honourable the Earl of Radnor, for granting a suitable site for the statue at Folkestone."

It was proposed by Dr. GLOVER, seconded by Mr. SIMON, and resolved: "That the warmest thanks of this meeting and of the subscribers at large are due and are hereby given to the Honorary Secretaries, George Eastes, Esq., M.B., F.R.C.S., and W. G. S. Harrison, Esq., Town Clerk of Folkestone, for the time and care which they have so freely bestowed on the Harvey Tercentenary Memorial Fund, and which have so largely contributed to its success."

It was proposed by Dr. O. REES, seconded by Dr. HADEN, and resolved: "That the best thanks of the subscribers are due and are hereby tendered to the auditors, Dr. C. J. Hare and Dr. J. G. Glover, for their valuable services to the Fund."

It was proposed by Mr. ALLINGHAM, seconded by Dr. HADEN, and resolved: "That the best thanks of the subscribers at large are due and are hereby tendered to the members of the London and Folkestone Executive Committees for their able services to the Fund."

It was proposed by Sir G. BURROWS, Bart., seconded by Dr. QUAIN, and resolved: "That the best thanks of this meeting are due and are hereby given to Dr. Risdon Bennett, both for his kindness in granting the College Library for the purposes of this meeting, and also for presiding on this occasion."

The meeting then closed.

It is computed that about £300 more are required to enable the Committee to carry out the wishes of the subscribers in a perfectly satisfactory manner.

#### MEDICAL QUESTIONS IN PARLIAMENT.

THE reports published in the daily papers of discussions in the House of Commons on matters affecting medical interests are commonly very much abbreviated, and often in condensation the sense and character of the discussion are much misrepresented. Many matters of great professional interest are altogether omitted, or briefly noticed in a line of passing comment. We have made arrangements for providing our readers with special reports of all such discussions. In another column will be found a full report of the discussion on the Army Medical Service on Thursday, June 13th, which passed almost unnoticed in the political papers.

#### EXAMINATIONS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following is a record of the results of the examinations during the collegiate year ending July next, to be presented to the next meeting of the Council, viz.: Numbers examined for primary membership, 746; of which 477 were approved, and 269 rejected. For *pass* membership, 533 candidates, 411 of whom received their diplomas, and 122 were rejected. For primary fellowship, there were 95 candidates, 46 of whom were approved, and 49 rejected. For final examination, there were 44 candidates, 33 being approved, and 11 referred. For the diploma in dental surgery, there were 32 candidates; 24 were successful, and 8 rejected.

#### THE LOST MEDICAL SCHOOL.

THE following notice appears in the *Oxford University Gazette* of June 18th.

3. *Mathematics and Physical Science*.—Regius Professor of Medicine: Henry W. Acland, D.M. The professor will be ready to receive members of the University who desire information or assistance in respect of the department of medicine on all Mondays in November, at noon, in the medical department of the museum. He will give clinical instruction in the infirmary on Saturdays, at 11.30 A.M., commencing November 2nd. Mr. W. F. Donkin, M.A., as deputy of the professor, will receive pupils in subjects connected with the public health in the sanitary laboratory of the museum. Members of the University who desire to attend any of the above are requested to enter their names in the Radcliffe Library at the museum on or before Saturday, October 26th.

This notice will be read with interest. We have already mentioned the course of things which has led to the extinction of the medical school of Oxford, the erasure of its medical faculty, and the relegation of the nominal relics of medical teaching to the department of mathematics and physical science. May it be hoped that some more practical result than hitherto will result from the stirrings of activity indicated in the notice of "assistance and advice", and "clinical instruction" in medicine, which are here given under the shelter of the heading Mathematics and Physical Science?

Where there is no medical school, however, there are not likely to be any medical students; and, seeing that neither human anatomy and physiology, the principles of therapeutics, medicine, nor surgery are taught at Oxford, notwithstanding the special endowments for the purpose and the great wealth of the University, it is difficult to find any serious purpose under the above solemn but curiously misplaced announcement. We give the notice as it has been forwarded to us; but what are we to read between the lines?

#### THE EMPEROR OF GERMANY.

IN explanation of the rather despondent bulletin recently issued by the Emperor's surgeons, we have, from an authentic source, some particulars of the very serious injuries inflicted by the dastardly attempt on his life, from which, as it will be seen, speedy recovery cannot be expected, and which must involve further surgical operations for removal of some of the imbedded shots. He is now considered to be, happily, out of danger. There are, however, six pellets of shot in the right forearm (the Emperor was struck while saluting from the left side); and one of these entered the joint of the wrist, where it remains without doing any harm. The other twenty-six grains of shot are in the skin of the neck, left cheek, and left shoulder. The Emperor was saved by wearing a helmet. Two buck-shot struck and perforated the helmet with such force that the brass helmet was fractured and pierced. One of these would have perforated the temporal bone. The Emperor lost much blood, but had no consecutive fever.

The physicians attending the Emperor William have this week issued the following statement.

"The undersigned consider themselves under an obligation to make the following declaration as a complement to the bulletins issued by them respecting the health of the Emperor-King, with a view to counteract various evasive and inaccurate versions of His Majesty's condition. By the merciful help of God, the course taken by the wounds and the entire illness which His Majesty has suffered through this most deplorable occurrence have been satisfactory almost beyond expectation. The various stages of the illness were noted in the bulletins which have been published. From this, it is by many hopefully and joyfully inferred that His Majesty will very shortly be completely restored to health. In present circumstances, the fulfilment of this hope is certainly the desire which animates the hearts of all. But, besides passing moments of pain, His Majesty suffers much from helplessness through being unable to use either arm; and his complete recovery can only be effected after a long time, during which many obstacles may have to be encountered, which, with God's help, we hope may be overcome as happily as those that preceded them, but cannot fail to inflict much pain upon the august patient.—Dr. LAUER, Dr. LANGENBECK, Dr. WILMS."

## ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL:  
NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 10th day of July next, at Two o'clock in the afternoon.

FRANCIS FOWKE,

*General Secretary.*

36, Great Queen Street, London, W.C., June 12th, 1878.

BRITISH MEDICAL ASSOCIATION:  
FORTY-SIXTH ANNUAL MEETING.

THE Forty-Sixth Annual Meeting of the British Medical Association will be held at Bath, on Tuesday, Wednesday, Thursday, and Friday, August 6th, 7th, 8th, and 9th, 1878.

*President:* M. A. EASON WILKINSON, M.D., F.R.C.P., Senior Physician to the Manchester Royal Infirmary.

*President-Elect:* R. W. FALCONER, M.D., F.R.C.P., D.C.L., Consulting Physician to the Royal United Hospital, Bath.

An Address in Medicine will be given by HENRY F. A. GOODRIDGE, M.D., F.R.C.P., Bath.

An Address in Surgery will be given by C. G. WHEELHOUSE, F.R.C.S., Leeds.

An Address in Forensic Medicine will be given by DOUGLAS MACLAGAN, M.D., F.R.C.P. Edin.

The business of the Association will be transacted in Five Sections, viz. :—

**SECTION A. : MEDICINE.**—*President:* T. Grainger Stewart, M.D., F.R.C.P. Edin. *Vice-Presidents:* B. Foster, M.D., F.R.C.P.; Thos. Clifford Allbutt, M.D. *Secretaries:* Thomas Cole, M.D., 17, Paragon, Bath; Chas. Albert Hingston, M.D., 3, Sussex Terrace, Plymouth.

**SECTION B. : SURGERY.**—*President:* G. W. Callender, F.R.C.S., F.R.S. *Vice-Presidents:* Furneaux Jordan, F.R.C.S.; W. Stokes, M.D. *Secretaries:* J. H. Morgan, F.R.C.S., 12, Chapel Street, Park Lane, London; J. F. Parsons, Esq., Frome.

**SECTION C. : OBSTETRIC MEDICINE.**—*President:* A. H. McClin- tock, M.D., LL.D. *Vice-Presidents:* James Watt Black, M.D.; H. Macnaughton Jones, M.D. *Secretaries:* Heywood Smith, M.D., 2, Portugal Street, Grosvenor Square, London; Henry Lawrence, Esq., 5, Unity Street, Bristol.

**SECTION D. : PUBLIC MEDICINE.**—*President:* J. T. Arlidge, M.D., F.R.C.P. *Vice-Presidents:* D. Davies, Esq.; Francis Thomas Bond, M.D. *Secretaries:* F. Vacher, Esq., 35, Hamilton Square, Birkenhead; W. Harling Sissons, Esq., 3, Priestgate, Barton-on-Humber.

**SECTION E. : PHYSIOLOGY.**—*President:* John G. McKendrick, M.D., F.R.C.P. Edin. *Vice-Presidents:* Henry Power, F.R.C.S. *Secretaries:* R. Shingleton Smith, M.D., Clifton, Bristol; A. E. W. Fox, M.D., 16, Gay Street, Bath.

*Honorary Local Secretary:* R. S. FOWLER, Esq., 6, Belmont, Bath.

*Tuesday, August 6th.*

11 A.M.—Service at the Abbey. Sermon by the Bishop of Bath and Wells.

2 P.M.—Meeting of Committee of Council.

4 P.M.—Meeting of the Council, 1877-78.

8 P.M.—General Meeting.—*President's Address.*—Annual Report of Council, and other business.

*Wednesday, August 7th.*

9.30 A.M.—Meeting of Council, 1878-79.

11 A.M.—Second General Meeting.

12 A.M.—Address in Medicine.

2 to 5 P.M.—Sectional Meetings.

9 P.M.—Soirée at the Assembly Rooms by the Mayor and citizens of Bath.

*Thursday, August 8th.*

9 A.M.—Meeting of the Committee of Council.

10 A.M.—Third General Meeting.—Reports of Committees.

11 A.M.—Address in Surgery.

2 to 5 P.M.—Sectional Meetings.

6.30 P.M.—Public Dinner at the Assembly Rooms.

*Friday, August 9th.*

10 A.M.—Address in Forensic Medicine.

11 A.M.—Sectional Meetings.

2 P.M.—Concluding General Meeting.

## EXCURSIONS.

Friday Evening.—Soirée at the Colston Hall, Bristol, by the Bristol members of the Branch.

On Saturday there will be excursions to Longleat, Bowood, Wells and Cheddar, Malmesbury, Berkeley Castle, and (if a sufficient number of excursionists) to the Valley of the Wye.

The Honorary Secretary will endeavour to arrange for gentlemen well acquainted with the locality to accompany the parties on each excursion.

Any information will be given by the Secretary to the Excursion Committee, 6, Belmont, Bath.

Members of the Association will receive cards for the above proceedings, evening meetings, etc., at the Assembly Rooms, Bath.

## ANNUAL MUSEUM.

The Tenth Annual Museum of the British Medical Association will be held at the Assembly Rooms, Bath, and will be open daily from 10 A.M. till 6 P.M., on August 6th, 7th, 8th, 9th, for the exhibition of the following objects :—

1. Latest Inventions in Medical and Surgical Instruments and appliances of all kinds.

2. New Chemicals and Apparatus; New Drugs and their preparations; and New Articles of Diet for Invalids.

3. Drawings, Diagrams, or Models illustrating the Ventilation of Hospitals and Private Dwellings.

4. General Pathological Specimens; with Photographic Models, Drawings, etc., illustrating disease; and Microscopic Pathological Specimens.

The following is a list of the Museum Committee, to any member of which communications, etc., may be addressed. Sections 1, 2, and 3: Dr. Spender, 17, Circus, Bath; F. K. Green, Esq., 3, Gay Street, Bath. Section 4: Dr. Cole, 17, Paragon Street, Bath; G. E. Lawrence, Esq., Claverton Street, Bath.

## NOTICE TO EXHIBITORS.

Application to be made as soon as possible, at the same time giving a list of objects, and mentioning the space required. Each object to be accompanied by a printed or written description attached to the article exhibited.

All parcels to be delivered on or after July 27th, and not later than August 3rd, and to be removed within three days after August 12th. They must be addressed to Drs. Spender and Cole respectively, at the Assembly Rooms, Bath. All expenses of carriage and all risk to be borne by the Exhibitors. A card bearing the name and address of the exhibitor to be enclosed in each package, ready to be fixed on the outside.

N.B.—Specimens and Instruments which have been exhibited at former meetings cannot be received on this occasion.

All communications to be addressed to Drs. Spender and Cole, as above.

## GLASGOW AND WEST OF SCOTLAND BRANCH.

THE annual meeting of this Branch will be held on Tuesday, the 25th instant, in the Faculty Hall, 242, St. Vincent Street, Glasgow, at 2 P.M.: Dr. ANDREW FERGUS in the Chair.

The subject of the Duke of Richmond's Medical Act Amendment Bill will be introduced; and it is expected that some interesting discussion will take place.

The members will afterwards dine together at 5.30.

Glasgow, June 18th, 1878.

## SOUTHERN BRANCH.

THE fifth annual meeting of this Branch will be held at Salisbury, on Wednesday, June 26th.

1 P.M.—Luncheon at the residences of Mr. Blackmore, Mr. Darke, Mr. Gowing, and Mr. Bennett.

2 P.M.—The general meeting will be held at the Council Chamber, and an address will be delivered by the President-elect, B. G. GOWING, Esq.

During the afternoon, the members will have an opportunity of visiting the Cathedral, the Blackmore Museum, and other places of interest in the locality.

The dinner will take place at the White Hart Hotel at 5 P.M. Tickets 15s. each, including wine.

J. WARD COUSINS, M.D., *Honorary Secretary.*

Southsea, June 18th, 1878.

## BATH AND BRISTOL BRANCH.

THE annual meeting of the Branch will be held at the Mineral Water Hospital, Bath, on Wednesday, June 26th, at 4.30 P.M., when H. MARSHALL, M.D., will resign the Chair to H. HENSLEY, M.D. The members will afterwards dine together at the York House.

R. S. FOWLER, } *Honorary Secretaries.*  
E. C. BOARD, }

Bath, June 4th, 1878.

## MIDLAND BRANCH.

THE annual meeting of the above Branch will be held in the Guildhall, Lincoln, on Thursday, June 27th, 1878, at 2 P.M.: President—C. H. MARRIOTT, M.D., Leicester; President-elect—A. MERCER ADAM, M.D., Boston.

After the transaction of the usual business of the Branch, the following papers will be read and discussed.

Cases of Obscure Diseases of the Liver, by Wm. Webb, M.D., Wirksworth.

Clinical Notes, by J. O. Brookhouse, M.D., Nottingham.

On the importance of establishing a temporary adhesion between the Upper and Lower Eyelids (Artificial Anchyloblepharon) in certain cases of disease, and in order to facilitate the performance of some plastic operations, with illustrative cases, by C. B. Taylor, M.D., Nottingham.

Demonstration of Dr. Howard's Direct Method of inducing Artificial Respiration, by J. Wright Baker, Esq., Derby.

The New Wards of the Stamford Infirmary: a contribution to Plans of Hospital Construction, by W. Newman, M.D., Stamford.

On Hospital Insalubrity, by T. Symptom, Esq., Lincoln.

Operations will be performed at the County Hospital at 11 A.M. The new County Hospital buildings are now completed.

Dinner at the Great Northern Hotel at 5 P.M. Tickets, 6s. each.

In order to facilitate arrangements, the Honorary Secretary will be obliged by receiving information from gentlemen who intend to be present at the dinner.

C. HARRISON, M.D., *Honorary Secretary.*

Lincoln, June 18th, 1878.

## LANCASHIRE AND CHESHIRE BRANCH.

THE forty-second annual meeting of this Branch will take place at the Assembly Rooms, Blackpool, on Friday, June 28th, 1878, at 1 P.M.; Dr. STEELE (Liverpool) President; Dr. LESLIE JONES (Blackpool) President-elect.

Dr. Leslie Jones will give an address, the Report of the Council will be read, and the ordinary business of the Branch will be transacted.

The following communications have been promised.

1. Mr. Reginald Harrison: On the Use of Filiform Bougies with Tunnell Instruments (Gouley's) in the Treatment of Stricture of the Urethra.

2. Dr. Haddon: 1. Two Cases of Ulcerating Endocarditis, with Temperature Charts and Sphygmographic Tracings; 2. An Easy Way of Noting Cases in General Practice.

3. Dr. Howie: The Grape-Cure in Bilious Nausea and Early Pregnancy.

4. Dr. Bennett: Chronic Cervical Metritis treated by Interstitial Injection coupled with Dilatation.

5. Mr. Lund will show a case of Contracted Fingers, and a case of Ankylosis of the Digital Joints, successfully treated.

6. The Report of the Duration of Intention Committee will be read, and a summary of the results obtained will be given.

Luncheon will be provided at the Assembly Rooms from eleven to one o'clock.

The members will dine together at Bailey's Hotel, at five o'clock. Charge 7s. 6d., exclusive of wine. Gentlemen intending to be present at the dinner are requested to forward their names to Dr. Leslie Jones, Blackpool, not later than June 24th.

D. J. LEECH, M.D., *Honorary Secretary.*

Manchester, June 13th, 1878.

## SOUTH EASTERN BRANCH.

THE annual meeting of this Branch will be held at the Greyhound Hotel, Croydon, on Wednesday, July 3rd, at one o'clock; Dr. LANCASTER of Croydon, President-elect, in the Chair.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, June 18th, 1878.

## SOUTH-EASTERN BRANCH.

A MEETING of the Executive Council of this Branch will be held at the Greyhound Hotel, Croydon, on Wednesday, July 3rd, at half-past twelve o'clock precisely.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, June 18th, 1878.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, July 2nd. The Chair will be taken by the President, SAMPSON GAMGEE, Esq., at 3 P.M.

An address will be delivered by the President-elect, Dr. TIBBITS, of Warwick.

The annual dinner will also take place at the Midland Hotel, at 5 P.M. precisely, for the convenience of country members. Dinner tickets, exclusive of wine, 7s. 6d. each.

JAMES SAWYER, M.D., } *Hon. Secretaries.*  
EDWARD MALINS, M.D., }

Birmingham, June 11th, 1878.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH.

THE annual meeting of this Branch will be held at Neath, on Thursday, July 11th: J. TALFOURD JONES, M.B., President; JOHN RUSSELL, Esq. (Neath), President-elect.

Any members desirous of reading papers, etc., are requested to communicate the titles to either of the Honorary Secretaries.

ANDREW DAVIES, M.D., } *Honorary Secretaries.*  
ALFRED SHEEN, M.D., }

June 12th, 1878.

## NORTH OF ENGLAND BRANCH.

THE annual meeting of this Branch will be held at Hartlepool, on Thursday, July 25th, at 3 P.M.

G. H. PHILIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, June 8th, 1878.

## METROPOLITAN COUNTIES BRANCH: ORDINARY MEETING.

AN ordinary meeting of this Branch was held at 11, Chandos Street, Cavendish Square, on Wednesday, May 22nd, at 8 P.M.; S. W. SIBLEY, Esq., President, in the Chair.

## VACCINATION.

Dr. J. GREENE (Birmingham) read a paper on Animal Vaccination, which is published at page 889.

Dr. E. C. SEATON read a paper on the Working of the Vaccination Law, which is published at page 887.

Dr. R. CORY said that it was known that cow-pox had been artificially produced by inoculating animals with the virus of small-pox; and thus it had been proved that small-pox could be converted into cow-pox. Again, it had been noticed by many observers on retrovaccination that the lymph, at its first removal, appeared to have undergone degeneration. He had used the Belgian lymph, and had found that the scars were small, and ran through their course more rapidly than those of ordinary lymph. One observer on animal vaccination had found that he could not transmit the lymph from calf to calf for more than ten generations; but, if children were inoculated with the lymph, it appeared to preserve its power indefinitely. Hence animal vaccination was a means of weakening the lymph, not strengthening it. By perseverance, however, and by a proper selection of cases, a weak stock of lymph might be improved. The only argument in favour of the adoption of animal vaccination was the transmission of syphilis, the risk of which, however, was extremely small.

Dr. J. W. TRIFE said that it had been very completely shown that vaccination with the human lymph in present use, if properly performed, was quite effective; and, therefore, it was unnecessary to go back to animal vaccination. Last year, he obtained permission of the London School Board to examine the children of a school in his district, and he found that twenty-five per cent. were inefficiently vaccinated; some had not been vaccinated at all, and others had very slight marks. The district-vaccinator vaccinated the children, but got no pay, having reported them as cases of revaccination. There ought to be better supervision over the vaccination-officers; they should not be under the control of the boards of guardians, but under that of the sanitary depart-

ment, and should be supervised by the medical officers. He did not blame them, or charge them with laxity in performing their duties; but they required better supervision, and he agreed with Dr. Seaton, that the number of vaccination officers was not sufficient. It was said that outbreaks of small-pox could not altogether be accounted for. But he thought that vaccination was done too imperfectly, and for too low fees. Again, if there were but one mark on the arm, the vaccinator, when he again operated, could not get pay, the case being regarded as one of revaccination. He thought that the epidemic of small-pox was not yet at an end; but it had not spread in his district as it did in 1871, because the cases had been isolated and removed early to hospital.

Mr. BONNEY called attention to the importance of revaccination. Practically, in the present epidemic, the public looked to the medical men to stop the course of the disease; and, it being supposed that they failed in doing this, a distrust of vaccination was being spread, which would be difficult of removal. He had removed many cases of small-pox from his district. When the epidemic broke out, if he had been able to vaccinate or revaccinate every person in his district, the disease would have been stamped out; but he was powerless. He was informed by the Local Government Board that they did not supply lymph for the purpose of revaccination.

Dr. SEATON said that the supply of lymph to individual vaccinators by the Government establishment could not be carried out unless a system of payment, etc., were adopted, which he would not like to see introduced. The public vaccinators, however, could make arrangements with the private practitioners for the supply of lymph.

Mr. BONNEY explained that he did not mean that the lymph should be supplied by the vaccination establishment to the practitioner for private purposes, but in aid of the performance of his public duties.

Mr. ALDERSON said that, while the present method of vaccination was successful, if done properly, he would not have recourse to animal vaccination. As regarded the supply, most medical men in good practice could supply themselves, taking care to use the lymph from children whose history was known. He had been able to supply himself and his friends with vaccine matter. He did not believe in the alleged insusceptibility to vaccination; he had failed three times in vaccinating a child, but had succeeded the fourth time. He never failed in vaccinating from arm to arm. He did not consider public superior to private vaccination. Public vaccinators had not time to go into the history of the children, and might thus disseminate the germs of disease. Revaccination ought to be carried out. He did not approve of the reduction of the number of vaccination stations. Every general practitioner ought to be allowed to vaccinate anyone who applied to him, and be paid by the Government for it.

Dr. DUCAT thought that, if public vaccination had not been taken from the district medical officers, the percentage of failures would have been much lessened. The medical officers of the districts would have a better knowledge of individual cases than the public vaccinators, and would be better able to avoid the selection of unhealthy subjects as vaccinifers. He was often in a difficulty when small-pox broke out from want of a supply of lymph. Again, the district medical officer met with many of the children not accounted for in the vaccination returns, but at present it was no part of his business to vaccinate them.

Mr. R. CEELY had used the lymph of Mr. Greene, Mr. Warlomont, and Dr. Martini with satisfactory results; but the lymph soon wore out unless there were a large stock for selection. Revaccination was a matter of very great importance; it should be cultivated and encouraged. He was much interested in the diminution of the efficacy of lymph by successive transmission through animals. All the animal lymph that he had received from Mr. Greene was as good as any that he had seen; but, without selection, it was liable to degenerate.

Mr. BROWNFIELD thought that, if the number of vaccinating stations were increased to any extent, there would be a difficulty in keeping up a supply of lymph. As regarded revaccination, the difficulty was the low rate of payment; the operation required more lymph and took longer time than ordinary vaccination.

Mr. BLACKMAN had been vaccinating for twenty years, and found the lymph as successful as at first. He was always glad to supply practitioners with lymph on Wednesdays, after he had secured a supply for himself. He thought that all public vaccinators should act in this way. There was a difficulty in getting persons to be revaccinated even from their own healthy children.

Mr. HUDSON said that one way in which small-pox was spread was the manner in which the patients were conveyed to hospital. He thought the age specified by law for revaccination was too far advanced; seven or eight years would be a very good time to begin. He had done revaccination in many cases, but had not been able to charge for it. Revaccination ought to be taken in charge by the Local Govern-

ment Board. He approved of the present system of vaccination; he had not a large district, but could always keep up a good supply. A system of weekly revaccination would be a good thing; but it was only in cases of epidemics of small-pox that people would attend to it.

Dr. HIBBERD was glad to hear that so small a proportion as five per cent. of the children escaped vaccination. It must, however, be remembered that, in some cases, births were not registered; and, in some instances, persons removed from one district to another, and the children were vaccinated twice; hence the number of cases of vaccination was liable to be apparently greater than it really was. He had been surprised at the number of unvaccinated children in schools. The vaccination officer or the medical officer of health should examine the children in schools, and the public vaccinator should be allowed to vaccinate them. Persons removing from a district should be required to register the fact, in cases of removal before a child was vaccinated.

Dr. DUDFIELD did not think that the public vaccinator had power to go into the houses in an infected district and vaccinate the inmates; but that the district medical officers could do this, and perform vaccination and revaccination.

Dr. W. V. LYLE thought the arm-to-arm lymph very good. He referred to cases of outbreak of small-pox in schools, in which the spread of the disease had been arrested by vaccinating other children.

Mr. GREENE wished that there had been more discussion on animal vaccination. He thought that there should be an opportunity of going to the cow from time to time when a supply was required.

Dr. SEATON would have been glad to hear more discussion on Mr. Greene's paper. He did not, however, admit that the prevalence of small-pox was due to the present system of vaccination. He would point out the duties of public vaccinators and district officers in cases of outbreak of small-pox. The vaccination officers were instructed by the Local Government Board to look up the children in the infected houses, and to give notice to the public vaccinator, explaining that the children could not be taken to the vaccinating station. A district medical officer attending a case of small-pox in any house was at liberty to vaccinate the other children, and was entitled to the same pay for this as the public vaccinator; but it was not compulsory on him to do so. In other words, a district medical officer *might* vaccinate the inmates of an infected house; a public vaccinator *must* do so, when the case was reported to him by the vaccination officer.

#### STAFFORDSHIRE BRANCH: ORDINARY MEETING.

THE third ordinary meeting of this session was held at the Board Room of the Mines Drainage Commissioners, 22, Darlington Street, Wolverhampton, on Thursday, May 30th, 1878; present, Dr. ARLIDGE, President, in the chair, and twenty-six members.

*New Members.*—The following members of the Association were duly elected members of the Branch: Mr. John Clare (Hanley); Mr. Dakeyne (Leek); Dr. Daniel (Stone).

*Medical Acts Amendment Bill.*—A memorial in opposition to the above was considered, and afterwards signed by the President on behalf of the members present. It was resolved that the memorial be at once presented to the House of Lords.

*Habitual Drunkards' Bill.*—A letter was read from Mr. STEPHEN ALFORD (London) which stated that Dr. Cameron would, on July 3rd next, propose in the House of Commons that the above Bill be read a second time; also the desirability of local members of Parliament being requested to be present that evening, and, if possible, to give their support to the Bill.

*Specimens.*—1. Mr. LAWSON TAIT showed an Ovarian Tumour.

2. Dr. MILLINGTON exhibited Ivory Dust, Chips, and Jelly.

*Communication.*—Mr. JOHN HARTILL (Willenhall) read a paper on Convulsions during Labour.

#### BORDER COUNTIES BRANCH: SPRING MEETING.

THE spring meeting was held at the Keswick Hotel, Keswick, on June 1st, 1878; Dr. LOCKIE, President, in the chair. There were present eighteen members and one visitor.

A considerable number of those present availed themselves of the invitation of the local members to drive round Derwentwater before the meeting commenced.

*New Members.*—Welby I'Anson, M.B. and C.M.; Charles A. Parker, M.D. and C.M.; and Thomas Hatfield Walker, L.R.C.P. and L.R.C.S.E., were elected members of the Association and Branch. Mark J. Symons, M.B. and C.M., was elected a member of the Branch.

*Representatives of the Branch on the General Council.*—The following gentlemen were elected: J. K. Burt, M.D.; J. Gilchrist, M.D.; S. Lockie, M.D.; M. W. Taylor, M.D.; R. Tiffen, M.D.

*Papers.*—The following papers were read.

1. The General Practitioner in his relation to Public Health and to Sanitary Officers. By Dr. KNIGHT.

2. Surgical Notes; Imperforate Anus; Inflammation of the Antrum; and Sayre's Treatment of Spinal Caries. By Dr. MACLAREN.

3. On the Removal of Cauliflower Excrescence of Uterus by Excision of the Cervix and by the *Ecraseur*, with Specimen. By Dr. TAYLOR.

*Habitual Drunkards' Bill.*—The following resolution, proposed by Dr. TIFFEN, and seconded by Dr. MACLAREN, was unanimously adopted: "That, in the opinion of this meeting, some legislative measure is necessary for the control and cure of habitual drunkards; and that the Habitual Drunkards' Bill, 1877, introduced into the House of Commons by Dr. Cameron, being calculated to secure this object, the Secretaries of the Border Counties Branch be instructed to request the local members of Parliament to support the second reading of the same."

*Dinner.*—The members and their friends dined together at 4 P.M.; Dr. Lockie in the chair, and Dr. Taylor in the vice-chair.

#### THAMES VALLEY BRANCH: ORDINARY MEETING.

A MEETING of this Branch was held at the Greyhound Hotel, Richmond, on June 13th; Dr. PRICE JONES in the chair.

*Papers.*—The following were read.

1. Mr. BALMANNO SQUIRE read a paper on the use of Chrysophanic Acid in Psoriasis and other Skin-Eruptions; and exhibited photographs, which showed the results of treatment.

2. Dr. ATKINSON read a paper on Vaccination and Revaccination.

*Dinner.*—The members and friends afterwards dined together.

#### EDINBURGH BRANCH: ANNUAL MEETING.

THE annual general meeting of the Branch was held at 5, St. Andrew Square on Tuesday. In the unavoidable absence of Sir ROBERT CHRISTISON, Dr. JAMES YOUNG was voted to the chair.

*The Report of the Treasurer* showing a satisfactory state of the funds was received.

*Officers.*—Sir Robert Christison, Bart., was re-elected President; Dr. Argyll Robertson and Dr. W. Rutherford were elected Vice-Presidents; Dr. Angus Macdonald, Dr. Brodie (Liberton), Dr. Blair Cunnynghame, and Dr. P. A. Young were elected members of the Council of the Branch.

*The Medical Act Amendment Bill.*—A letter was read from Dr. Waters (Chester), asking support to the Medical Reform Bills now before Parliament. It was agreed that the letter should lie upon the table.

*Habitual Drunkards.*—Letters were read from Mr. Alford, asking the Branch to petition in favour of the Habitual Drunkards' Bill. The Chairman was empowered to sign and forward a petition in the name of the meeting; and the members present undertook to use their influence to obtain other signatures to the petition.

After a vote of thanks to the Chairman, the meeting separated.

## CORRESPONDENCE.

### PROXY VOTING AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

SIR,—It has been suggested to me that it would be desirable, in connection with the above-named matter, that petitions, as numerous as possible, should be presented at the time of the election of members of Council. I enclose a copy of a petition which will, I should imagine, meet the case. If you will publish the copy I enclose, I would ask the Fellows in various towns to copy and sign. If, then, they are forwarded to Sydney Jones, Esq., 16, George Street, Hanover Square, London, W., or to myself, they will be presented at the time of election.—I remain, yours obediently,

GEO. JACKSON, F.R.C.S.Eng. (Exam.)

18, George's Terrace, Plymouth, June 18th, 1878.

\* To procure any important number of signatures to petitions, it is usually necessary to circulate copies separately to those whose signatures are desired.—ED. B. M. J.

### To the President and Council of the Royal College of Surgeons.

We, the undersigned Fellows of the Royal College of Surgeons, desire to bring under your notice the hardship and inconvenience which the Fellows of the College who reside at a distance from the metropolis labour under in exercising the right they possess of voting at the election of members of the Council. As matters stand at present, they cannot exercise their right of voting except at the expense and loss of time involved in a journey to London. Your petitioners pray that such an alteration in the by-laws be made as to permit Fellows who are prevented from any cause from attending the meeting to vote by voting-papers, properly attested, or by proxy.

### THE BILL OF THE MEDICAL REFORM COMMITTEE OF THE BRITISH MEDICAL ASSOCIATION.

SIR,—The Medical Reform Committee of the British Medical Association has drafted a Bill for the amendment of the Medical Act of 1858, and it was introduced into the House of Commons by Messrs. Mills, Childers, and Goldney, and read a first time on 29th May last. This Bill provides for an uncontrolled free trade in medicine and surgery by any persons whomsoever, provided they do not take or use recognised medical titles. It permits persons holding disreputable foreign qualifications to take medical titles, and to practise under these titles just as freely as they please. It permits the Medical Council to register foreigners who hold no medical qualifications whatever. It permits registered medical men to fill up death-certificates in cases they have themselves never seen, but which have been attended by unqualified assistants who have never had one hour's medical education. It deprives persons of the power of prosecuting in cases of the grossest violation of its own provisions, without their at first going through the tedious and expensive process of obtaining the sanction to the prosecution of the Medical Council. In short, the best and most vital interests of the profession are surrendered as a concession for securing a representation of the profession upon the Medical Council—a representation which might turn out, even after all the fuss that has been made about it, to be a sham and a delusion, both mortifying and ludicrous.

The Government Bill, taken as a whole, is an exceedingly bad Bill; but this Bill of the Medical Reform Committee, so far as its supposed maintenance of the interests of the profession are concerned, is simply an infamous Bill.—I am, sir, your obedient servant,

June 17th, 1878.

R. H. S. CARPENTER.

P.S.—A little confusion appears to exist about the three Bills now in the House of Commons. Dr. Lush's Bill is Bill No. 1; Bill No. 2 is the Bill I am condemning; the other has come down from the Lords, and is not known by any number.

### IS ALCOHOL FOOD?

SIR,—How Dr. A. Carpenter could have tortured anything in my note into an accusation of falsehood against himself, is beyond me to conceive. Let me assure him that the last thing in my mind, when I wrote it, was any thought of want of honesty in his statement. To question the value of the data on which a writer bases his conclusions is surely not to accuse him of untruth. On the face of the matter, as it stands at present, it is patent that the truth or otherwise of the assertion, that human life can be sustained for many months on alcoholic drinks alone, rests wholly on the averments of the drinker and his friends. Dr. A. Carpenter accepts such evidence as conclusive. I venture to say that it is not sufficiently trustworthy, nor rigid clinical proof such as science has a right to demand. If, as he says, cases of the kind are known to every medical man in extensive family practice, there should be no difficulty in finding proof abundant and overwhelming. But where is it? I took the liberty of asking Dr. A. Carpenter to give the data on which he framed his assertion, and he does so in your last number. Your readers can judge their value. He says that he has under his charge a patient who, "during three months, did not take two ounces of any other kind of food than stimulants. There was no deception in the case". But does Dr. A. Carpenter really say that the scientific world is to accept as a fact the food-power of alcohol on such a bare statement as this—on evidence supported wholly by the assertions of the drinker and his friends? He also refers to the cases of "two old ladies who lived on stimulants alone for several weeks before death, and I have no reason to suppose that I was deceived by the attendants". Further to strengthen his position, Dr. Carpenter adds: "Almost every large private lunatic asylum will probably contain cases which are of a similar character."

When I said that, until better informed, I should doubt whether a single case of the kind which would satisfy clinical demands could be

produced, I had in mind that a discussion on this very subject took place many years ago, and that no such case was then produced, nor, as far as I know, has one been recorded to this moment.

There is another fact touching the history of cases of this kind to which Dr. Carpenter has not referred, and that is the length of time which men and women have lived, under certain conditions, without either food or drink. Certainly, men buried in a mine have lived for "several weeks"—three weeks, as recorded. And Dr. Willan relates the case of a young self-starving religious maniac, in whom life was prolonged for sixty days, nothing else being swallowed except a little orange-juice.

In his *Physiology*, Dr. W. B. Carpenter says summarily: "There is no reason to believe that alcohol, in any of its forms, can become directly subservient to the nutrition of the tissues...It may be certainly affirmed that it is incapable of transformation into albuminous compounds, and there is no sufficient evidence that even fatty matters can be generated in the body at its expense." Such, I believe, is the opinion of our best authorities on the value of alcohol as food. Dr. A. Carpenter will, I am sure, on reconsideration, admit that evidence much more complete than any which exists is required to establish the assertion that alcohol is a food.—Your obedient servant,

W. O. MARKHAM.

London, June 17th, 1878.

## REPORTS OF SOCIETIES.

### EPIDEMIOLOGICAL SOCIETY.

WEDNESDAY, JUNE 12TH, 1878.

JOHN MURRAY, M.D., President, in the Chair.

*Epidemic of Small-pox.*—Dr. McCOMBIE read a paper on comparison of the small-pox epidemics, 1871-1876. After stating that the statistics on which the paper was based were exclusively those furnished by the reports of the medical superintendents of the hospitals of the Asylum Board, he indicated that it would be advisable that the official statistics of the Board should be constructed on an uniform plan, and hoped the managers would take this into their consideration. He then proceeded to indicate the points of interest to be noted in a comparison of two epidemics of small-pox, and hoped that some indication might be afforded from the experience of the present epidemic as to the working of the Vaccination Act of 1871. The proportion of vaccinated to unvaccinated cases remained the same as in 1871; but, while this was so, it was found that in the present epidemic a much larger proportion of vaccinated and unvaccinated (7 per cent. and 11 per cent. respectively) were attacked with small-pox under fifteen than in 1871. Dr. McCombie said that one would have expected that the natural result of the Vaccination Act would have been to increase the proportion of vaccinated admissions, but one would hardly have expected that the number of those attacked under puberty would have increased to the extent named. Under fifteen, it was to be observed that in the unvaccinated cases there was an increase in 1876 over 1871 to the extent of 11 per cent., and this is due in great measure to an increase of 7 per cent. in the admissions under five years of age in 1876 as compared with 1871, and this was precisely the period during which the Vaccination Act of 1871 had been in operation. Of the mortality in the respective epidemics, it was seen that the present was less fatal than the last only to the extent of 1 per cent.; but that the death-rate in the vaccinated was 2 per cent. less than in 1871, and that of the unvaccinated 1 per cent. greater. The mortality in the unvaccinated had risen from 37 per cent. in 1836 to 45.5 per cent. in 1876. Analysing the mortality under fifteen, it was found that in the vaccinated it was much less than before, and especially in those under five years of age; while in the unvaccinated it was much the same as in 1871. With regard to protection afforded by good and bad marks under ten years, it was found that those who were badly vaccinated ran no more risk of contracting small-pox than those well vaccinated, although the mortality was greater in those with bad marks. It seemed that the numbers of the vaccinated under five attacked with small-pox were largely on the increase; and, while this was a disappointing fact, it was encouraging to know that the mortality had diminished considerably. On the subject of revaccination, some particulars were obtained from the Asylum Board reports. While it was the unanimous testimony of the medical superintendents that none of the staff who had been revaccinated contracted small-pox, Drs. Collie and Layton recorded instances of patients who had been successfully revaccinated being attacked, and it would seem conclusively to be shown that revaccination was not absolutely preventive of small-pox, although severe or fatal cases after it were rare, and in these the operation had probably been performed under puberty.

Dr. McCombie then gave some statistics of the black or hemorrhagic form of small-pox. Of 121 cases, 64 were vaccinated and 57 unvaccinated. Under puberty, 33 per cent. were vaccinated; over puberty, 60 per cent. The majority of the vaccinated had bad marks, though two had four good, and others a less number of such marks. No mention is made of this form of small-pox after revaccination. From the fact that many vaccinated people fell victims to the black small-pox, some had supposed that vaccination had no influence over it; but it would be quite as reasonable to say that vaccination did not protect generally against the mild or the severe forms of small-pox because in a certain proportion of cases it failed. Good vaccination was absolutely protective against no form of small-pox, but the number of malignant cases with such vaccination was few. That this form of small-pox was more common than formerly was the opinion of those who had had experience of both epidemics; but it did not necessarily follow that vaccination was losing its protective power.

### MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS IN IRELAND.

WEDNESDAY, MAY 1ST, 1878.

AQUILLA SMITH, M.D., in the Chair.

*The Prevalence of Small-pox in Dublin.*—Dr. T. W. GRIMSHAW opened a discussion on the present epidemic of small-pox in Dublin with an elaborate paper, in which he especially considered the questions: how the epidemic arose, how it has been promoted, how it may be ameliorated, and how similar outbreaks may in future be prevented. As to the relation between the prevalence of small-pox and the progress of the practice of vaccination in Ireland and in Dublin, statistics compiled from the Reports of the Census Commissioners show that deaths from small-pox decreased in the decade 1861-71 to one-tenth what they were in the decade 1831-41. These facts might, of course, be accounted for by some on the supposition of some obscure epidemic influence; but they were accounted for in a most satisfactory manner by the progress of vaccination during these decades. During the decade 1841-51, the first Vaccination Act—namely, the 3rd and 4th Vic., cap. 29—came into force in Ireland, and public vaccinators were provided by the Poor-law guardians; and thus vaccination was offered, but not made compulsory on the people. The result of affording these facilities was, that vaccination became more general, and the average death-rate from small-pox fell from 7.095 to 5.842 per 10,000 living. During the decade 1851-61, further facilities for vaccination were afforded by the passing of the Medical Charities Act, 14 and 15 Vic., cap. 68, by Clause 13 of which every dispensary medical officer was "required to vaccinate all persons who came to him for that purpose". Thus, all excuse for neglect of vaccination was removed by the State—the result being that this provision was largely availed of, and the average death-rate from small-pox fell from a ratio of 5.842 to 2.195 per 10,000 living. During the decade 1861-71, a most important change took place in the vaccination laws. On January 1st, 1864, during the prevalence of small-pox, the Compulsory Vaccination Act, 26 and 27 Vic., cap. 52, came into force, so that, during seven years of this decade, all persons born were bound to be vaccinated. The result of the enforcement of this Act was remarkable; for, during the decade, the mortality from small-pox fell to an average of 0.759 per 10,000 living—the total number of deaths returned to the Census Commissioners being but 4,113, of which 1,274 occurred before the Act came into force. In 1868 and 1869, vaccination had become very low in Dublin; in 1870, a few cases of small-pox appeared, and slightly stimulated vaccination; in 1871, a considerable number of admissions to hospital further stimulated vaccination, but it was not until after the disease had become widespread in 1871 that vaccination became excessive (if he might use the term). Thus, small-pox had reached its height before vaccination had reached its height. The present epidemic might be said to have commenced in July 1876, when two foci of the disease were established—one on the north, and the other on the south side of the river Liffey; both having originated through contagion introduced from Lancashire. About eighteen months, however, elapsed before the outbreak assumed formidable proportions. Its progress might be easily measured by the number of small-pox patients admitted month by month to Cork Street Fever Hospital, Dublin, viz.: October 1877, 3; November, 8; December, 23; January 1878, 19; February, 76; March, 106; April, 173. Up to March 31st, 1878, the records of Cork Street Hospital showed that, since the commencement of the epidemic in the autumn of 1876, 293 cases were admitted. The percentage of each variety of the disease was—discrete, 44.0; confluent, 50.3; and malignant (or purpuric and hemorrhagic), 5.7—compared with 61.8, 31.7, and 6.5 respectively, in the epidemic of 1871-73. The

mortality was 15.8 per cent. against 21.6 per cent. in the former epidemic. Not only was the total rate of mortality lower, but the mortality in each class was less. The mortality among the confluent cases showed a marked reduction from 47.6 to 21.6. This was easily accounted for by the fact that, of the confluent cases in 1871-73, only 60.1 per cent. were vaccinated; whereas, in the present epidemic, 70.1 were vaccinated. In the discrete variety, the mortality was, as usual, insignificant. The death-rate was 1.5 per cent. Of discrete cases, 5.1 per cent. were vaccinated. Among the confluent cases, only 7.1 per cent. were vaccinated; of these, 32 died, or at the rate of 21.6 per cent.; the rate of mortality of the vaccinated being only 9.4 per cent., while among the unvaccinated it was 51.1 per cent. Among the confluent cases, the mortality among the vaccinated was only 66.6 per cent., against 90 per cent. in the unvaccinated. Adding all classes together, the mortality among the vaccinated was only 6.8 per cent., against 50 per cent. among the unvaccinated. Up to the present, there had been only one case admitted to Cork Street Hospital who had been vaccinated. The author next considered what measures should be taken to avoid such visitations in future, and to limit the extent of the epidemic. He asked the chief promoting cause of which was the neglect of vaccination. He pointed out the following defects in the Irish vaccination laws:—*a.* A child may remain unvaccinated for a period of six months after its birth without its parents incurring any penalty. This is not in England is but three months. *b.* Public vaccinators in Ireland have no power to take lymph as in England, thus limiting considerably the supply. *c.* There is no inspection of vaccination in Ireland. *d.* The payments to public vaccinators in Ireland are so small that it is not worth their while to be zealous in the discharge of their duty. More than a year ago, a Bill to remedy these defects was drafted by the Council of the Irish Medical Association and presented to the Government, as also a Bill for consolidating and amending the vaccination laws in Ireland. No step has yet been taken to bring either of these Bills before Parliament. Besides neglected vaccination, the following causes of small-pox existed in Dublin which did not require any new enactment for their removal: 1. The disgraceful sanitary state of the city, as evinced by its high death-rate; 2. The want of proper sanitary organisation and supervision; 3. The want of proper means of removing infected persons to hospital; 4. The want of epidemic hospital accommodation; there being but one epidemic hospital in Dublin, and it not sufficiently large to cope with such an epidemic as the present.—Dr. HAYDEN said the first point that struck him was, what the paper proved as to the great value of vaccination, rather than being a mortality than in preventing attacks of the disease. There could not be a doubt that where persons had been previously vaccinated the mortality was less than it would otherwise have been. On the other hand, every year's experience tended to show that the value of vaccination as a preventive measure was less than had been supposed. The small-pox had been imported. Then it was clear that it had a favourable soil to nestle in, and had become rapidly developed, owing to the degraded state of the city as regards vaccination and isolation. Hence it had been promoted was clear. People were not aware of the danger of intercourse with persons suffering from the disease. In two or three cases, he had seen the most extraordinary reluctance on the part of patients to be sent to hospital. There was also great danger from convalescent patients. Poor people returned home in the stage of desquamation, and with their clothes infected; and there could not be a doubt that the disease had been extensively propagated by the contact of clothes with them.—Dr. LATOR said it seemed to be the general opinion that the best means of preventing the extension of small-pox was to prevent susceptibility by vaccination and revaccination, and also to isolate convalescent hospital, and cut off the sources of the disease.—Dr. MAC SWINLEY observed that, notwithstanding the apparent clearness of the proof that the present epidemic had been introduced from Ireland, it was possible it might have arisen in some quarters from France.—Dr. ASHLE spoke of an outbreak which had occurred four years ago in the Londonderry District Lunatic Asylum, in the presence of which he vaccinated the people as rapidly as he could.—Dr. HENRY R. HENRY said he wished he could put implicit confidence in vaccination as regards the keeping away of small-pox. In his opinion, the chief vaccination was the modification of the disease. He had met with pustules in the arch of the aorta and in the mucous membrane of the throat.—Dr. CHURCHILL did not think vaccination could prevent small-pox; but a mere scrape on a person's arm was not a vaccination if it had been properly performed—a specific cicatrix was not apparent. He approved of revaccination.—Dr. FINNY believed that revaccination was of the utmost importance in preventing the spread of the disease. He thought the idea that vaccination absolutely protected from small-pox was exploded. Isolation of small-pox patients was of the utmost importance, and so was the destruction of

their clothing. The last should be especially insisted on, as anyone acquainted with the poor knew that they would rather give the clothes of a member of a family who had died of scarlatina or small-pox to some other member of the family than destroy them. In former epidemics of small-pox, chicken-pox was very prevalent, and he looked on chicken-pox as a very mild form of small-pox.—The CHAIRMAN said he was sure small-pox pustules would be found in the aorta more frequently than they were if they were looked for, and also on the mucous membrane. He knew of a case of a lady who had natural small-pox five times, and died of the fifth attack. He entirely concurred in the statement that in a great many instances failure in vaccination arose from want of skill on the part of the vaccinator; and he believed that a great deal of the small-pox arose from defective vaccination.—Dr. GRIMSIAW said he had no doubt that revaccination put a stop to small-pox. As to the question of revaccinating people in the presence of small-pox, his opinion was that, whether small-pox were present or not, they should be revaccinated. He did not believe in the separate identity of chicken-pox. Small-pox attacked the inflamed eyes of strumous subjects.

The Society adjourned for the session.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, June 13th, 1878.

[SPECIAL REPORT.]

*The Army Medical Service.*—In Committee of Supply, on the proposal of a vote of £256,500 for the medical establishment and services, Mr. PARNELL said he wished to ask the Secretary for War whether the vote included any charge on account of hospital services in connection with the brigade of guards. He might mention, by way of explanation, that, whilst discussing the previous vote, before the right honourable gentleman came into his present position, the then Secretary for War stated that a portion of the stock-purse fund only was put down in vote 1 under certain headings, and that the remaining portion of the fund was distributed throughout the other votes. He (Mr. Parnell) was anxious to know in what votes the remaining portion of the stock-purse fund appeared, as he had not been able to trace it.—Colonel STANLEY said that that portion of it which related to medical purposes, such as hospital expenses, was included in the present vote; but he could not at the moment recollect under what heads the remaining portion of the fund appeared.—Mr. PARNELL said the precise information he wanted was this: whether the vote included any charge on account of hospital service in the brigade of guards.—Colonel STANLEY said he would endeavour to answer the question. He believed that the stock-purse defrayed all the medical charges of the guards, but, whether the actual surgeons doing duty there were included, he was not able to say. His impression, however, was that they were.—Mr. PARNELL said the right honourable gentleman did not seem to be aware that the original stock-purse fund, known as such, had been broken up into portions and distributed amongst certain items in the votes. He had been successful in tracing two items in vote 1, and perhaps he might be allowed to refer to them, as they might be a guide to the right honourable gentleman. In vote 1, there were, according to page 16, three portions of this stock-purse fund included, namely, £2,610 for contingent allowances, etc.; £700 for allowances in aid of band expenses; and £6,910 for the profits of the field officers of the foot guards in the shape of extra pay. Perhaps it would be better to take the items in order as they appeared on the vote. The first was infantry and foot guards' profits of the field officers in the shape of extra pay, £6,910; then, under the head of contingent allowances, deducting stoppage for repair of arms, £2,610; and then, under the head of allowances for band expenses, came the sum of £700. These were all the items which stood opposite an entry under the head of infantry and foot guards; and it was found out, in the course of the discussion of vote 1, that these items were paid out of the stock-purse fund. The right honourable gentleman the then Secretary for War further informed the Committee, that the remnants of the stock-purse fund, which amounted to considerably more than these three items—the total amount of the fund being £13,190—was distributed among the rest of the votes. According to a return which had been produced at the instance of the honourable member for Clonmel, he found that the remainder of the fund was applied to hospitals and recruiting purposes. The sum of £8,925 was applied to hospital purposes for the brigade of guards, and the sum of £145 was applied to recruiting purposes for the same brigade of guards, making a total of £9,074. He had been very anxious to trace this vote, and to find out what had become of the different items of this stock-purse fund; and he would have been able to obtain information, no doubt, if the former

Secretary for War had been still in office. At present, he would direct the attention of the Secretary for War to page 29, which referred to the present vote—vote 4. He found, under the head of allowance to private medical practitioners and medical bills, under subhead c, for home purposes, an item of £5,340, and for colonial purposes £5,840. There was an increase in the item for home purposes for last year of something like £2,300, and an increase in the item for last year for colonial purposes of something considerably more than that. He could understand that the vote for colonial purposes would be still more increased by the war at the Cape; but he could not understand the reason for the other increase, and, in any case, he could not account for the sum proposed to be applied. In the return produced at the instance of the honourable member for Clonmel, there was a sum of £3,000 odd, which was stated to be taken for hospitals in connection with the guards. He wished to know what had become of the sum applied to the hospitals of the guards.—Colonel STANLEY was afraid that he was not able offhand to trace the particular item. If he had been in the House when the previous discussion took place, his attention would have been directed to the subject probably, but unfortunately he was not. He thought the honourable member would find that provision was taken for part of this vote in the shape of hospital services in one vote, and in other shapes in regard to the other votes.—Mr. PARNELL: Which votes?—Colonel STANLEY said the honourable member would see that provision was taken for medical services in vote 4, and so on in regard to the other votes. He was unable to give more precise information at the present moment; but if the honourable gentleman would put the question on the report, he would then be able to give him every information in regard to the matter. He believed the way in which the vote is applied was traceable, though in the form in which it originally stood in vote 1, it was unquestionably open to some doubt. He would repeat the answer he had given to a previous question, that his impression was that the hospital services of the year were recorded in the vote about to be taken.—Mr. PARNELL said the difficulty he found himself in was this, that the whole of the stock-purse fund had been broken up. It was originally in one lump sum of £13,190; and a return was moved for by his honourable friend the member for Clonmel, asking for further details as to the appropriation of the fund and the application of the money. When the return appeared, it was found that it only accounted for a very small portion of the sum of £13,190; in point of fact, it only accounted for £502 18s. 4d. for pay and allowances, apartments for the field-major, fuel and light, recruiting, proceedings at courts-martial, etc. Altogether, there were five items, and they amounted to £502 18s. 4d. But the vast bulk of the sum of £13,000 was not accounted for at all, and was still put down as the stock-purse fund, so that, as far as any information to be obtained from the return was concerned, they might just as well have been without it. In consequence of the futility of the return, his honourable friend moved for another. The second return went much more into detail, but did not clear up this extraordinary matter, which was of a very complicated character, and very much required to be cleared up, and with regard to which he would suggest by and by a way of clearing it up. In the second return obtained by the honourable member for Clonmel, he found that this sum of £11,000 and odd, not accounted for in the preceding return, was accounted for in the following manner: the hospital services of the guards were to cost £3,929, recruiting services £145, band expenses £1,360; in addition to which, there was an item of £970 for staff allowances to non-commissioned officers, and an item of £6,708 5s. 6d. for average profits of field-officers and captains. It was not his present purpose to object to these large profits of field-officers and captains, though he thought they should be done away with after the present officers ceased to hold their offices. He wished more particularly to direct the attention of the right honourable gentleman to the hospital branch. They had there the expenses of hospitals and a number of contingencies, wages, washing, fuel, light, repairs, etc., amounting altogether to a sum of £8,029. Now, that amount had been stowed away somewhere, and he did not know where. It was not in vote 1, because they had accounted for that item, and he thought that a considerable portion of it must be in vote 4. The difficulty he felt was this, that when the report was brought on it was always difficult to discuss a question of this sort, because the report itself was not brought up until very late. He would suggest to the right honourable gentleman that, if he were unable to point out in this vote for medical establishment and services what portion of the sum of £8,000 and odd was included, he should postpone the vote until some future day.—Colonel STANLEY said he could not accept the suggestion. He had already endeavoured to explain, though he was afraid without success, to the honourable member that, so far as he was aware, charges which were made upon the stock-purse fund, except those which were included in vote 1, already voted, were distributed among the separate votes of the

estimates; that was to say, in the hospital vote the item for provisions, light, forage, fuel, and so forth, belonged to the stock-purse fund. He was not able to say precisely the amount of the charge included in each vote; but if the honourable member would be good enough to repeat his question on report, he should be glad to give every information. In the meantime, he had endeavoured to answer the question by stating that, to the best of his belief, the medical officers were included in the previous vote; that was to say, that the medical expenses were included in the present vote, and that the rest of the stock-purse charges, such as fuel, light, etc., were to be found in the other votes.—Colonel ARMITAGE said he had intended raising a question touching the medical department upon this vote, but, when he saw a matter brought forward in such a cavilling spirit, he had changed his mind, and abstained from occupying the time of the Committee with the subject. He was anxious to do all he could to forward the estimates, but he reserved to himself the right of using an independent member's day for the purpose of calling attention to the state of the medical department. He wished his right honourable friend to regard this intimation as made in a friendly and not an unfriendly spirit. He had no wish to interfere with any of the steps that were now being taken for the reorganisation of the department. His only object was to improve the present state of things.—Lord ELCHO said he had listened to what had been brought forward by the honourable member for Meath, and he could not help agreeing that the question was a very important one. On the other hand, it was not desirable that they should unduly interrupt the supply. It appeared to him that the question had been fairly met by the officers of the Secretary of State. He would, therefore, suggest to the honourable member for Meath that he should allow the vote to pass, on the understanding that the information would be given on the report.—Sir GEORGE BALFOUR said the honourable member for Meath had a perfect right to ask for information. It was certainly within his (Sir G. Balfour's) own knowledge that the origin of all the evil was allowing the Guards to conduct their own offices. In point of fact, the Guards had been allowed from time immemorial to manage their own offices, and the consequence had been a confusion of accounts. The Secretary for War had now, with the honesty that was characteristic of the right honourable gentleman, proposed to give all the information asked for, and he thought the honourable member for Meath ought not further to oppose the vote.—Mr. PARNELL said the only reason why he appeared to hesitate about accepting the offer of the right honourable gentleman was because he very much feared, from what he had previously seen in regard to the question, that the right honourable gentleman would not be able to give him the information he required. The subject was really in such a ravel and a tangle, that until a new arrangement was made to place the officers of the Guards on the same footing as the officers of the rest of the army, it would be impossible to make head or tail out of this question of the stock-purse fund. This last attempt of the Government to distribute the items among the other votes instead of making them one bulk sum, only made confusion worse confounded. In point of fact, he did not think the right honourable gentleman knew very well what he was talking about when he answered the question in the first instance. The money was obviously hidden away, and where, as the right honourable gentleman the Secretary of State for War himself admitted, he did not know.—Mr. BIGGAR said the difficulty that was found in connection with all these votes was this. The honourable and right honourable gentlemen who had charge of the different departments were almost all new to their particular positions, and were quite as destitute of information as the House itself. He did not wish to make any special charge against the Government on this question, because he was disposed to make every allowance for the Secretary for War, but it was a very serious position to find themselves placed in, that on all occasions when a question was asked in reference to different departments they should receive the same answer from the honourable and right honourable gentlemen in charge of them. The evil was that they came into office since the estimates were framed, and that they did not know anything about them. Whenever information was asked for the practice was to say, "I really do not know anything about it; but if you will postpone the question until the report, then I will give you the information required." When the report came on, if they repeated the question, they were told that it would be wasting time to discuss it, and that the only time for raising the question was when the vote itself was brought forward. He would suggest to the Government that it would be well to postpone all these votes until the heads of the different departments got to know something about the subjects they had to bring before the committee. As the matter existed at present, there was a frightful waste of time involved, because the House was unable to get any information, and at the same time, the non-official members who really knew a good deal more about these matters than

the heads of the departments, did not wish to press too hardly upon gentlemen who were new to their offices. At the same time, he really did think that that system of asking time after time for the postponement of questions until the report, when it was well known there could be no opportunity for discussing the question, was most objectionable and ought to be given up.—Major NOLAN was sorry that the honourable member for Hereford had not brought the question of medical officers before the Committee. He also regretted that the members of the medical profession who were also members of the House, and who sat principally on the Opposition benches, were not present when the vote was under discussion. In their absence, he desired to bring forward a question which considerably affected the interests of medical officers, and which had been a subject of comment during the last two or three years. It was alluded to very recently in a letter that appeared in the newspapers from Sir D. Corrigan. The question to which he referred was that of providing a supply of surgeons for the army. It was a question in which great interest was taken by the medical profession generally, and particularly by what might be called the Medical Schools. The Irish members had a good deal of interest in the matter, because a large proportion of the surgeons of the army came from Ireland. The letter to which he referred really summed up the whole subject. It showed that there was at present a great want of medical officers in the army, and it put forward, as the chief reason, not the want of pay or of material advantage, but the fact that the medical officers in the army were not properly treated. One grievance was, that they were required to cease to be members of regiments and members of messes, this being carried out by an order of the Secretary for War. Personally, he (Major Nolan) had taken great pains at various times to put the question to various army surgeons with whom he had been brought into contact, and he certainly found that all the younger members were unanimous. The older members of the army medical profession took the same view, although perhaps not so strongly. All the younger medical men, however, felt very strongly indeed upon the fact that, at the present moment, they were not members of regiments and had no *locus standi*. They found that when they went into a mess, they had, as it were, no home. An ordinary officer had his home and his mess to which he could ask his friends, but the army medical officers were only there on sufferance and could ask no friends. He hoped the right honourable gentleman would read the very important letter to which he had referred, which fully summed up the views of the surgeons in the army. He (Major Nolan) had no doubt that it was a real grievance, and the effect of it was witnessed by the diminished number of candidates for appointments in the army. He believed that if it went on much longer the Army Medical Department would drift into a state of hopeless inefficiency. He was satisfied that the condition of the medical profession in the army would be much different if the Government would adopt measures for improving the present status of the medical profession. If something of this kind were not done, the army itself would suffer in the end, because if the country went into war, the medical department would certainly break down. It would be of no use then for Her Majesty's ministers to say it was not their fault, that they were anxious to employ the men if they could procure them. It would be the fault of the Government entirely if they did not take proper precautions to secure an efficient establishment in a time of peace. It was impossible to get an efficient staff in a time of war, because it required a certain amount of discipline, and civilian practitioners obtained on the spur of the moment would require considerable time and training before they could be rendered efficient. He believed that the application of the regimental system as far as medical officers were concerned would be wise economy in the end. The hard work entailed by the business of an efficient staff told hardly upon the private soldier as well as upon the surgeons themselves. At present, there were not a sufficient number of medical officers to enable them to obtain proper leave, and the whole of the profession was in consequence greatly dissatisfied. He was sorry that his honourable friend the member for Galway (Dr. Ward) was not present, because he knew that he was anxious to bring the question forward. In the absence of his honourable friend, he (Major Nolan) had ventured to introduce the question, and he would only add that, in regard to the medical officers themselves, they were all of them unanimous upon the subject. He wished to ask what steps the Government intended to take in the matter.—Colonel STANLEY said the House was already aware that his noble friend and predecessor had already referred to a small committee the very important case of the medical officers of the army, and had issued general instructions to that committee to confer with all the large medical centres, with eminent physicians, and the principal medical councils, so as to ascertain really what, in the eyes of the profession, were the practical difficulties in the way of obtaining a sufficient

supply of medical officers for the army. Of course, they all had a certain bias in the matter, and however carefully they might endeavour to weigh the question, they would have a prejudicial feeling either one way or the other. It must be borne in mind that the present system was adopted after very careful consideration. It was adopted mainly in consequence of the action taken by a number of the members of the profession in the view of what they regarded as their grievances. His predecessor in the office of Secretary for War, after weighing fully the representations of the profession and considering how their grievances could best be met, came to the conclusion that they were only to be met by the rearrangement of the medical service on a basis very distinct from that which they had hitherto obtained. Whatever merits might attach to the regimental medical service, Lord Cranbrook considered that it was not absolutely perfect with regard to the position of the officers in the regiment. All these things had to be considered carefully, and to be carefully weighed as to how they would press upon particular cases. But they would never be able to meet the individual grievances of everybody in a department of this sort. On the other hand, if it were possible to place these gentlemen on a satisfactory footing—if they found that the complaints were such that they could be fairly met—he should not scruple to come down to the House and venture to suggest a solution to the problem. At the present moment, however, he was speaking in the dark.—The right honourable gentleman continued: The hospital system, not only in military and naval but in civil life, is altering from day to day, and I am not at all prepared to admit that it is in the naval and military services alone that you find medical men who are dissatisfied with their respective positions. So far as the actual shortness of numbers goes, I may say that that is a difficulty we experience in common with all other countries. We are taking the best means in our power to meet the deficiencies when they occur. We are considering the views brought before us, and I can only say this, that no one has a more sincere desire to meet the medical profession than I have. I only hope that I shall receive such advice and assistance in the matter of evidence and otherwise as will enable me to put my hand on the defects that exist; but at the present time, I really do not feel justified without this evidence in prejudging the question to any extent. I am anxious to give it most careful consideration.—Lord ELCHO: Before the Committee passes this vote, there is one point to which I should like to draw the attention of the Secretary of State—a matter affecting the health of the troops in India. An important correspondence has been going on between His Royal Highness the Field-Marshal Commander-in-Chief and a field officer, with reference to the hour at which the soldiers should have their dinners in India. The field officer to whom I refer, who has had some experience in one of the most unhealthy parts of India, has found that through postponing the dinner-hour to three or four o'clock, his regiment has not suffered from those complaints that troops are usually subjected to in India. I should like to ask the Secretary of State whether his attention has been called to the correspondence in question.—Colonel ARBUTHNOT: May I ask whether this Committee that is sitting is likely shortly to complete its report?—Colonel STANLEY: Yes.—Colonel ARBUTHNOT: And whether it will be possible for us to see it, or whether it will be a private departmental report?—Colonel STANLEY: I cannot answer the last question, because it will depend on the form, not the substance, of the answers that will be received by the Committee from the medical profession. As to the report, I believe it will be complete shortly. The form in which eminent medical men in civil life may give their evidence may be of a confidential character. If it be not, I shall be happy to make the report public.—The vote was then agreed to.

*Medical Act, 1858, Amendment (No. 2) Bill.*—Mr. A. MILLS moved the second reading of this Bill.—Mr. W. H. JAMES thought that some explanation should be given of the objects of the Bill, and that it should not be read a second time without some statement.—Mr. A. MILLS said the Bill was almost identical with one which was introduced on a previous occasion (Lord Ripon's Bill of 1870). Its object was, among other things, to provide for a conjoint scheme of examination which would provide an uniform system, and also provide that there should be a direct representation of the medical profession in the medical councils and boards. The Bill also dealt with various medical and surgical qualifications. There were further provisions with regard to Colonial registration, etc. The measure was identical with the Bill introduced by the Government, with the exception of the provision for the direct representation of the profession on the Medical Council.—Sir CHARLES DILKE said he did not think the House ought to go on with a Bill of that kind at such an hour as that (half-past one). They understood they would have a very large and important measure of the Government on that subject, which they had already seen, because it had been printed in another place. It was a very intricate

and important matter, and dealt with a subject on which the Government had expressed their intention of legislating. Until they had the Bill before them, so that they could compare it with the Government Bill, he did not think they should go on with it, and therefore he would move the adjournment of the debate.—Mr. A. MILLS said he had no objection, and the second reading of the Bill was therefore adjourned.

*Thursday, June 20th.*

**Army Medical Service.**—Mr. MITCHELL HENRY: I beg to ask the Secretary of State for War whether the new warrant respecting the medical service of the army will include the first batch of those gentlemen who entered the medical service under the ten years' system; and if not, whether he will take their case into consideration.—Colonel STANLEY: I have read the question of the honourable gentleman so far as concerns the existence of any new warrant; and what I have to say is this. There is a Committee now sitting to inquire into the position of medical officers of the army, and until that Committee has reported, I am not in a position to say what can be done in the case of those or other officers concerned. There is no warrant in contemplation at this moment.

## PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

### REPORTS OF MEDICAL OFFICERS OF HEALTH.

**KING'S NORTON.**—Mr. Hollingshead estimates the birth-rate at 36.3 and the death-rate 15.06 per 1,000 in 1877, against a birth-rate of 43.3 and a death-rate of 20.15 per 1,000 in 1876. The zymotic death-rate has been increased partly by seven deaths from typhoid fever, which were caused by the distribution of polluted milk in two villages; so that it was 3.07 per 1,000, against 2.23 in 1876. The death-rate of infants under one year was 10.4 per 100 births. There were five deaths from diphtheria, against one in 1876; but no special cause is pointed out, although the connection between deaths from zymotic diseases and imperfect drainage is especially mentioned. The water-supply of the district is chiefly derived from wells placed near to the houses and badly constructed, and the drainage of several of the villages is described as being very unsatisfactory.

**DERBY.**—This is the first annual report that has been presented to the Council by Mr. Iliffe, who estimates the population at 53,841, and states the registered births to have been 2,221 and the deaths 1,131, giving a birth-rate of 41.2 and a death-rate of 21.0 per 1,000 inhabitants. The deaths of children under one year were at the rate of 24 per cent. of the total deaths and 12.2 per cent. of the births. The deaths per 1,000 population from seven principal zymotic diseases were 2.4, from pulmonary diseases (other than phthisis) 3.6, from tubercular diseases 3.5, and from wasting and convulsive diseases of children 3.6, which latter is rather high. There were nineteen deaths from typhoid fever, which are less than usual, and were nearly all caused, in Mr. Iliffe's opinion, by imperfect sanitation, such as open cesspools, middens, etc., in close proximity to dwellings and drinking-wells; by bad connections with the sewers, allowing the entrance of sewer-gas; and other objectionable arrangements.

**GREENOCK.**—Dr. Wallace reports that the death-rate for April was 23.4 per 1,000 population, which is in excess of that for March. Diseases of the respiratory organs were unusually prevalent and fatal, owing to the cold and variable weather then prevalent. Croup and diphtheria caused five deaths, without any information being given as to the drainage of the houses; but there was no death from small-pox, typhoid, or measles. Dr. Wallace also states that 80 per cent. of the cases of infectious diseases were reported to him by the householders, which is very satisfactory.

**SCARBOROUGH.**—The meteorological table shows that the mean temperature at this seaside place was in defect half a degree for the whole year, and as much as 3.9 degrees in May and 2.3 in August, whilst it was 2.2 degrees above the mean in November. The rainfall amounted to 31.0 inches. There were 849 births and 469 deaths registered during the year, 54 of which occurred from zymotic diseases. The death-rate including visitors was 19.67, and excluding visitors 18.95, per 1,000 population.

## MEDICAL NEWS.

### MEDICAL VACANCIES.

The following vacancies are announced:—

- BIRMINGHAM GENERAL HOSPITAL**—Assistant-Physician. Salary, £100 per annum. Applications to be made on or before the 26th instant.
- BRIGHTON HOSPITAL FOR SICK CHILDREN**—House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing.
- CLOGHER UNION**—Medical Officer for Ballygawley Dispensary District. Salary, £100 a year, with £15 as Sanitary Officer, and the usual Registration and Vaccination Fees. Applications to be made to the 1st proximo.
- COUNTY AND COUNTY OF THE BOROUGH OF CARMARTHEN INFIRMARY**—House-Surgeon. Salary, £125 per annum, with lodging.
- DROGHEDA UNION**—Medical Officer for St. Peter's East Ward Dispensary District. Salary, £115 per annum as Medical Officer. £20 as Sanitary Officer, with Registration and Vaccination Fees. Personal attendance of candidates necessary on the day of election: viz., the 25th instant.
- EAST RIDING LUNATIC ASYLUM**—Medical Superintendent. Salary, £550 per annum, with furnished house, coals, and gas. Applications to be made on or before the 26th instant.
- GREAT NORTHERN HOSPITAL**—Surgeon to the Out-Patients' Department. Applications to be made on or before July 2nd.
- HOSPITAL FOR SICK CHILDREN, MANCHESTER**—Junior Resident Medical Officer. Salary, £20 per annum, with board and residence. Applications to be made on or before the 25th instant.
- HULL GENERAL INFIRMARY**—Assistant House-Surgeon. Salary, £50 per annum, with board and lodging. Applications on or before July 8th.
- KENMARE UNION**—Medical Officer for Kenmare Dispensary District. Salary, £100 a year, with £25 as Sanitary Officer, and the usual Registration and Vaccination Fees. Applications on or before the 26th instant.
- KENT AND CANTERBURY HOSPITAL**—Physician. Applications to be made on or before the 26th instant.
- LONDON FEVER HOSPITAL**—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance.
- MAGHERAFELT UNION**—Medical Officer for Monymore Dispensary District. Salary, £115 a year, with £15 as Sanitary Officer, and Registration and Vaccination Fees. Election will take place on the 25th instant.
- MALE LOCK HOSPITAL, Dean Street, Soho**—House-Surgeon. Salary, £5 per annum, with board and lodging. Applications on or before July 22nd.
- MANCHESTER ROYAL INFIRMARY, DISPENSARY, and LUNATIC HOSPITAL**—Ophthalmic Surgeon. Applications to be made on or before the 25th instant.
- MIDDLESEX HOSPITAL**—Assistant-Physician. Applications to be made on or before July 2nd.
- NEWCASTLE-UPON-TYNE BOROUGH LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £100 per annum, with board and lodging. Applications on or before July 22nd.
- OWENS COLLEGE, Manchester**—Junior Demonstrator in Anatomy. Salary, £100 per annum. Applications on or before July 15th.
- RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY AND SEAMEN'S INFIRMARY**—Resident Medical Officer. Salary, £150 per annum, with furnished apartments, gas, firing, and attendance. Applications to be made on or before July 1st.
- SALFORD AND PENDLETON ROYAL HOSPITAL**—District Surgeon. Salary, £20 per annum, with board and lodging. Applications on or before July 2nd.
- ST. MARYLEBONE GENERAL DISPENSARY**—Honorary Physician. Applications to be made on or before July 1st.
- SEAMEN'S HOSPITAL, GREENWICH**—House-Physician. Salary, £75 per annum; and House-Surgeon, salary, £50 per annum, with board and lodging in each case. Applications to be made on or before the 27th instant.
- SOMERSET COUNTY LUNATIC ASYLUM**—Assistant Medical Officer. Salary, £100 per annum, with board, residence, and washing.
- SOUTH DEVON AND EAST CORNWALL HOSPITAL**—House-Surgeon. Salary, £20 per annum, with board. Applications to be made on or before July 8th.
- WEST BROMWICH DISTRICT HOSPITAL**—House-Surgeon. Salary, £100 per annum, with board and residence. Applications on or before July 1st.
- WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL**—House-Physician. Salary, £100 per annum, with board, washing, and apartments.—House-Surgeon. Salary, £100 per annum, with board, washing, and apartments.—Honorary Physician. Applications to be made on or before the 24th instant.

### MEDICAL APPOINTMENTS.

*Names marked with an asterisk are those of Members of the Association.*

- AMFLETT, Edward, M.A., M.D.**, appointed Assistant-Surgeon to the Central London Ophthalmic Hospital.
- CANTON, G. Anderson, M.R.C.S.I.**, appointed Honorary Dental Surgeon to the Royal Isle of Wight Infirmary, Ryde.
- \*CHURTON, T., M.D.**, appointed Honorary Physician to the Leeds Fever Hospital, *vice* C. Chadwick, M.D., D.C.L., F.R.C.P., resigned.
- EDGE, James J., L.R.C.S.I.**, appointed Resident Medical Officer to St. Mary's Hospital, Manchester, *vice* F. H. Folkes, L.R.C.P.Ed., resigned.
- JOHNSTONE, J. Carlyle, M.B., C.M.**, appointed Assistant Medical Officer to the Fife and Kinross District Lunatic Asylum.
- LEAHY, Albert W. D., L.S.A.**, appointed Resident Surgical Officer to Charing Cross Hospital.
- LE QUESNE, Edwin, L.R.C.P.**, appointed Resident Medical Officer to the Jersey General Dispensary, *vice* Henry Dugan, M.R.C.S.Eng., resigned.

Pear, James A., M.B., appointed Surgeon to the Dublin Throat and Ear Hospital, and Kendal Franks, M.D., resigned, on appointment as Surgeon to the Adelaide Hospital.  
 R. v. Charles S., M.D., appointed Assistant at the Physiological Institute of the University of Strassburg.  
 Wickes, Henry Adolphus, M.R.C.S. Eng., reappointed Resident Medical Officer to Charing Cross Hospital.

## BIRTHS, MARRIAGES, AND DEATHS.

*The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.*

### MARRIAGE.

POWELL-ADCOCK.—On the 17th instant, at All Souls, Langham Place, London, "Lilied Lewis Powell, M.R.C.S., L.R.C.P., Melton Mowbray, to Jessie Kate, only daughter of W. Adcock, Esq., of North Lodge, Melton Mowbray.—No cards.

TESTIMONIAL TO DR. STANISTREET.—Last week, a most gratifying address, signed by Lord Talbot de Malahide and some of the most influential inhabitants of Malahide and its neighbourhood, together with a purse of sovereigns, was presented to Dr. Stanistreet, in recognition of his unwearied attention to his duties as Medical Officer of the district for a period of nearly twenty years.

ST. THOMAS'S HOSPITAL.—The annual distribution of prizes to the students of this Hospital took place on the 7th instant, before a large assemblage. The prizes were presented by Mr. Le Gros Clark, F.R.S., Consulting Surgeon to the Hospital; and Mr. Alderman Stone, the Treasurer, presided, supported by several of the Governors, the President of the Royal College of Surgeons, the Master of the Apothecaries' Company, etc. After the presentation, the Dean (Dr. Ord) referred to the progress of the School, not only in numbers, but also in the spirit of inquiry and original investigation amongst the students. The Chairman congratulated his colleagues on the progress of the School, which he could confirm from his experience, and considered that only one requirement remained unfulfilled to render the School complete—viz., residential accommodation for the students, which he hoped would some day be accomplished. A vote of thanks to the Treasurer and to Mr. Le Gros Clark was proposed by the Dean and carried unanimously, and the proceedings then terminated.

COTTAGE HOSPITAL AT KEITH.—A bazaar was held at Keith, Banffshire, on June 11th and 12th, for the purpose of supplementing the funds already subscribed to erect a cottage hospital there. Drs. Struthers and Stephenson of Aberdeen delivered admirable opening addresses, which were attentively listened to by large audiences. The sum of £950 was realised, which, with former subscriptions, brings the amount available for building and endowment to upwards of £2,000.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following are the names of the eligible Fellows who are candidates for seats in the Council of this College at the ensuing election on Thursday, the 4th of July next, at 2 o'clock P.M.: 1. W. J. Erasmus Wilson, F.R.S., Henrietta Street; 2. Henry Lee, Savile Row; 3. Barnard Wight Holt, Savile Row (retiring from the Council in rotation); 4. John Gay, Tinbury Place South, nominated by John Wiblin, Southampton; Thomas Green, Bristol; James F. West, Birmingham; Jonathan Hutchinson, Cavendish Square; Henry Smith, Wimpole Street; William Adams, Henrietta Street; 5. Joseph Lister, F.R.S., Park Crescent, nominated by William Cudge, Norwich; Jonathan Hutchinson, Cavendish Square; William Mac Cormac, Harley Street; T. W. Nixon, Stratford Place; Thomas Smith, Stratford Place; M. Berkeley H. Wimpole Street; 6. Thomas Bryant, Upper Brook Street, nominated by Edward Cock, Dean Street; George Lawson, Harley Street; W. D. Hasland, York; Thomas Longmore, Netley; Thomas Smith, Stratford Place; Joseph Fayer, Granville Place; 7. Henry Thompson (Kt.), Wimpole Street, nominated by Thomas Bryant, Upper Brook Street; Christopher Heath, Cavendish Square; William Cudge, Norwich; George W. Callender, Queen Anne Street; William Mac Cormac, Harley Street; T. Pringle Teale, Leeds; 8. John Wood, Harley Street, nominated by William Cudge, Norwich; T. W. Nixon, Teale, Leeds; Jonathan Hutchinson, Cavendish Square; A. E. Durham, Brook Street; Christopher Heath, Cavendish Square; George W. Callender, Queen Anne Street; 9. Henry Power, Great Cumberland Place, nominated by Cesar H. Hawkins, Grosvenor Street; Thomas Smith, Stratford Place; Thomas Symptom, Lincoln; John Wood, Wimpole Street; Christopher Heath, Cavendish Square; Arthur E. Durham, Brook Street; 10. Edward Lund, Manchester, nominated by Edward Cock, Dean Street; Alfred Willett, Wimpole Street; John Wiblin, Southampton; T. H. Bartleet, Birmingham; Reginald Harrison, Liverpool; Arthur E. Durham, Brook Street. The Fellows will dine together at the Albion Tavern the same evening, when Mr. F. Le G. Clark, F.R.S., will take the chair.

## OPERATION DAYS AT THE HOSPITALS.

MONDAY..... Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.  
 TUESDAY..... Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.  
 WEDNESDAY.. St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.  
 THURSDAY.... St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.  
 FRIDAY..... Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.  
 SATURDAY.... St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

FRIDAY.—Quekett Microscopical Club (University College, Gower Street), 8 P.M. Mr. Frank Crisp, "On the Influence of Diffraction in Microscopic Vision".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with Duplicate Copies.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

TUPELO-TENTS.—In the notice of tupelo-tents in the *JOURNAL* of June 8th (page 823) we accidentally omitted to state that they were introduced into this country by Messrs. Salt of Birmingham.

### BRITISH PHYSICIANS ABROAD.

SIR.—Can you or some of your readers tell me under what restrictions and regulations an English medical man can practise in France, and in Switzerland?—I am, etc., R. R. S.

\*.\* In France, he must either obtain special permission of the Minister, which was formerly accorded readily to any suitably qualified physician, but is now rigidly withheld, or he must pass the examinations of the Faculty. In Switzerland, we are not sure how the matter stands, but we believe that a similar rule prevails.

S. J. (Devonport).—Taking them in seniority, the following are the members of the Council of the Royal College of Surgeons residing in the country, viz.: Mr. Hancock, Andover, Hants; Mr. Le Gros Clark, St. Leonard's-on-Sea; Dr. G. M. Humphrey, Cambridge; Mr. Baker, Birmingham; and Mr. Wheelhouse, Leeds; to which list may, it is hoped, be added the respected name of Mr. Edward Lund, Manchester, the President of the Surgical Section of the British Medical Association at the last most successful meeting in that town. He is a Fellow of the College by examination.

### MUSCÆ VOLITANTES.

SIR.—Your correspondent Mr. Strong, in his letter which appears in the *JOURNAL* of June 15th, seems to imply that all persons perceiving muscæ in their own eyes must necessarily be jaundiced. I should like to ask him how he would account for their presence in my case, when I tell him that I have been a teetotaler for the last ten years, during which time I think I may safely say that I have abstained from all the articles of food which he mentions, or at least most of them, yet I can discover no symptoms of jaundice in my system; and the muscæ, from which I have suffered all my life, have remained obstinately by me.

As regards a theory of my own, to which I drew attention in a former letter, and which, I think, is now pretty generally accepted by ophthalmists—viz., that the muscæ proper are simply blood-corpuscles, how would Mr. Strong account for their presence in the "aqueous humour"? Is it due to the bursting of a minute capillary through "over-distension"?—I am, sir, your obedient servant,

F. R. GREENWOOD, M.R.C.S.

St. Bartholomew's Hospital, June 17th, 1878.

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to **Mr. FOWKE**, not later than *Thursday, Twelve o'clock*.

**DR. PIERCE, THE DENBIGHSHIRE CORONER, AND THE LATE INQUEST AT RUTHIN.**

**SIR,**—Having read in a recent number of your *JOURNAL* a summary of the proceedings at the above inquest, with your unfavourable comments upon the conduct of the coroner—based, doubtless, upon the one-sided reports supplied to you—I beg leave to place before your readers a few facts and observations, which may set in a more favourable light the reputation of a gentleman who has been most unjustly assailed. After having fully investigated the case, and spoken to several gentlemen who were present during the inquiry, I have come to the conclusion that the coroner's conduct was not simply free from blame, but was really beyond all praise. He not only elicited the true facts of the case, which is the main object of an inquest, but he fully maintained the dignity of his court by his intelligence, impartiality, and firmness. The "scenes" which occurred were the result of something approaching to a conspiracy to defeat the ends of justice. On the one hand, there seemed to be a desire to conceal a dereliction of duty on the part of certain officials; and, on the other, a determination to punish a harmless creature who was not responsible for her acts. The coroner had to conduct his inquiry impartially in the midst of these adverse interests—hence the unseemly disturbance.

The facts of the case were these. A half-idiot woman had the misfortune to bear an illegitimate child, and, while nursing it, was taken with her baby to a house where two bedridden women were the only inmates. While in that house, the child was neglected, and, after a lapse of time, died through the want of nourishment and proper nursing.

**Mr. Henry Davies**, who was prominent among the disturbers of the court, had volunteered his services as a witness without being summoned in the usual way by the police or the coroner. He had visited the house as nuisance-inspector; knew that the child was being neglected, and dying of want and proper treatment, and that there was no one to look after it but an imbecile woman. **Mr. Humphrey Roberts**, clerk to the guardians, was also present, and took upon himself to interrupt the course of the inquiry. He wished to make a statement. The coroner replied that he could not permit him to do that, but that he might be examined upon oath, and might ask any questions of the witnesses which he thought fit. **Mr. Roberts** complained, in an excited manner, that the coroner had allowed the inquiry to take place without giving notice of it either to him, as clerk, or to the Board of Guardians; and that he had, in his opening address, spoken against the guardians, which he (**Mr. Roberts**) thought was wrong, and very unfair. The coroner, in a kind and mild way, requested **Mr. Roberts** not to go any further, or he would have to be committed for contempt of court. It was not his (the coroner's) duty to give him or any one else notice of the inquisition. He also reminded him that he, as clerk to the guardians, and the relieving officer, had been among the first to be informed of the case, and he must, too, have known that the coroner had been told by the police of the death of the child, and that an inquest would be held. The court was one of inquiry, and he (the coroner) would be sorry to accuse any one. He had told the jurors while the relieving officer was being examined that the guardians, and especially the relieving officers, had rules from which they could not deviate. He had certainly drawn the attention of the jury to the fact that it was their duty to try to find out the cause of the great delay there had been from the time when the case had been first reported, to the time when the deceased had been taken to the workhouse. The relieving officer's attention was first drawn to the case by police-constable Hughes on February 12th, and on the 13th it was reported to him (**Mr. H. Roberts**). On March 1st, the medical officer (**Dr. Jones**) received an order to attend the deceased, whom he saw the same day. **Dr. Jones** entered the case in his report-book, and placed it before the guardians, and recommended that the deceased should be taken to the workhouse; but this was not carried out until the 5th April, about seven weeks from the time the case was first noticed, and on the 7th April the child died.

The other disturber of the peace was a jurymen of the name of **Mr. Goodman Jones**, who, it appears, had not been summoned by the police, but had put himself on the jury unasked, his appointment being challenged in open court. He again showed an eagerness to criminate the lunatic mother by declaring his intention to bring witnesses to prove the bad conduct of the woman. The coroner very properly told him that it was not right for him, as one of the jury, to interfere and seek for witnesses, for that it was his duty to hear with an unbiased mind the evidence of witnesses brought in by the police. This jurymen, with others of a like mind, refused to sign the inquisition, drawn out in a legal and formal manner, and expressed thus: "That the said Edward Davies, on the 7th day of April, through the want of the common necessities of life and proper nursing, did die"; etc.; and wanted to substitute for it their own simple verdict of "Died from starvation and neglect". The coroner had to explain to them that, although the latter was their verdict, he was responsible for the proper wording of the inquisition, and he pointed out to them how he was obliged to qualify the words they had used in giving their verdict; as, for instance, the word starvation might be applied in the case of a perfectly well fed and well cared for person who had been frozen to death. Some of the jurors at first even objected to those words which are requisite to the completion of all inquisitions—"And so the jurors aforesaid, upon their oath aforesaid," etc.

Looking calmly over the whole of the circumstances, seeing that the coroner had to conduct his inquiry in the midst of conflicting motives and interests, I cannot find anything in this instance to detract from the fair fame to which he attained after the great Abergele inquest, when the press of England and Wales paid the highest tribute to his "coolness, experience, perception, and tact"; and, if anything, it has enhanced his estimable qualities of "amiability, kindness of heart, and sympathy with the suffering". His address at the opening of the adjourned inquest, when the limits of the inquiry were distinctly defined, his control over the exuberance of witnesses, the insolence of officers, the ignorance of jurymen, and the judicial summing up of the evidence, were characterised with that determination to find out the truth, and to do justice regardless of personal consideration, which have been the leading features of **Dr. Pierce's** long official career.

The newspaper which has been the chief means of circulating certain reports of the Ruthin inquest has been actuated by an evident animus against **Dr. Pierce**, which may have had its origin in a recent libel case, from which the doctor came out triumphant, and during the hearing of which the unfortunate publisher received a severe rebuke from the Lord Chief Justice.

In the alleged starvation case now referred to, the coroner's conduct has been completely vindicated by the report of the medical officer, who has since declared the unhappy mother in question to be a lunatic, not fit to be at large, and by the decision of the guardians, who have ordered her to be confined under proper treatment in the union workhouse.

The Abergele inquest was admitted to be one of the most difficult ever held in this country. **Dr. Evan Pierce** officiated there as coroner; and his medical knowledge, as well as his judicial ability, helped to unravel the complications of that mysterious accident to the satisfaction of all concerned. The jurors on that occasion passed an unanimous vote of thanks to him in the form of an addendum to their verdict, in which they said: "We have known the coroner for the last twenty years, and his ability and integrity are well known; and in the present inquiry his foresight, great forbearance, judgment, and determination have been most clearly shown, and he really deserves the thanks of the public as well as the jury." At the following quarter sessions, held at Wrexham, the chairman proposed a vote of "confidence in the ability and integrity of the coroner" (**Dr. Pierce**), which was seconded by the Lord-Lieutenant of the county, supported by **Sir W. W. Wynne, Bart.**, and carried unanimously. At first, several parties were dissatisfied at Abergele; but the relatives of the deceased and their professional representatives, which at one time numbered between thirty and forty, admitted at the close of the inquiry that everything had been conducted in the most satisfactory manner.

By this time **Dr. Pierce** has been thirty years a coroner, and during that period has conducted several important and difficult cases with signal success. He is proverbial for keeping up the dignity of his court, and is commended for wisdom and coolness, but he cannot bear any unwarranted interference with his authority. He has studied well the laws of evidence, and has mastered thoroughly every detail appertaining to the conduct of his court. His depositions and inquisitions are taken in the most accurate form, and he has been complimented by several judges of the superior courts for the correct manner in which these forms are returned by him.

When all the facts are known, it will be seen that the coroner was perfectly justified in threatening to commit for contempt of court certain parties who would not otherwise submit to the Ruthin inquest. Instead of being censured for not keeping up the dignity of the court, and showing proper respect for himself, it is the opinion of those most familiar with the proceedings, and who know the coroner best, that he only erred on the side of leniency towards the disturbers of his court.

Thanking you for an opportunity of defending one who is an honour to the medical profession, and who, as a coroner, has done, in his limited sphere of labour, as much good, proportionately, as **Dr. Lankester** and **Mr. Wakley** did in theirs, I am, sir, yours faithfully,

P. MOSTYN WILLIAMS.

Rhyl, June 1878.

**SIR,**—I shall be obliged if any of your readers can inform me if there be an institution into which can be received a soldier invalided from paralysis.—Yours obediently,

J. C. J.

#### CHOLECYSTOTOMY.

**SIR,**—I have had three cases very like that reported by **Dr. Sims** in his interesting article in your issue of June 5th. In none, however, were the gall-bladders so much distended as in **Dr. Sims's** case. I removed the contents of the gall-bladder by aspiration on several occasions—in one of them, without any benefit to the patient. I did not operate on the other two. All three died. I was not able to make out the exact hepatic disease present, as I did not dare to look for a *post mortem* examination, for the following reason. Some years ago, the Irish Local Government Board called on me to resign for getting a patient to will me a *post mortem* examination of his body. The result has been, that I have been since placed in doubt as to whether a necropsy would be allowed to me under any circumstances. I often thought that the ductus communis might have been closed in these cases by some adhesions capable of being broken through if the bladder were opened, or by a gall-stone removable under like circumstances. It is to be regretted that a complete necropsy was not obtained in **Dr. Sims's** case.—Yours,

Cashel, Ireland, June 10th, 1878.

THOMAS LAFFAN.

**ERRATUM.**—In the *JOURNAL* of June 5th, page 845, column 1, line 9, for "pathological" read "physiological".

#### WHO IS A PHYSICIAN?

**SIR,**—We hear enough of the right, or rather want of right, of gentlemen with the F.R.C.P., M.R.C.P., and L.R.C.P., calling themselves "Doctors"; but, may I ask, if an M.D. who has not also F.R.C.P., M.R.C.P., nor L.R.C.P., has any right to style himself a "Physician"?—I am, yours faithfully,

IN DUBET.

**A MEMBER (Birkenhead).**—Honorary degrees conferred without examination are not registrable qualifications at present.

#### BEDS FOR FEVER HOSPITALS; AND DRY-HEAT DISINFECTORS.

**SIR,**—In your issue of June 5th are two inquiries from a Medical Officer of Health. Your correspondent asks, What is the best material with which to stuff the beds of a fever hospital, and which is the best dry-heat disinfector? As both these questions were presented to me for solution a short time since, when I was consulting the Birkenhead Fever Hospital, I think I am in a position to answer them. At first I tried chaff-beds, but the trouble of frequently destroying the parasites and refilling the beds was inconvenient; and no doubt it would have been difficult to obtain sufficient supplies of chaff all the year round. I next used straw; I substituted curled hair; and as this is easily cleansed, not very absorbent, and improved by the patients, I have no reason to be dissatisfied with it. These dry-heat disinfectors, I believe, a simple iron box, heated by gas, is from 2 ft. in length, and fitted with a thermometer. I had such an one made for me by a local smith in this town, and it answers the purpose for which it was intended admirably well. In length and breadth it is a little larger than an ordinary single bed, being four feet and a half deep. It opens from the top, the lids being 2 ft. apart, and counter-weights, opening and shutting quite easily; an arrangement by which the space is economised, and the danger and inconvenience of swinging doors is avoided.—I am, sir, yours very sincerely,

—I am, sir, yours very sincerely,

CHARLES V. B. G.

Birkenhead, June 12th, 1878.

**MR. ROTHEN (Preston).**—Daily received; an I marked for 1878.

#### REMOVAL OF THE TONGUE.

**SIR,**—A member asks what I mean by a blanket pin. In reply, I beg to state that, in purchasing the article at a draper's shop, I asked to see one very large pin, and I was shown some two-and-a-half inches in length, and otherwise proportioned to an ordinary pin, and was told, or I understood, that they were called blanket pins. The second question—Why I transfixed the tongue with the pin? I answer by saying, that it was to form a fixed boundary to prevent the cord slipping forward. I would have "A Member" note, if he wish to perform the operation as I did, that I transfixed the tongue and placed the cord around its base, ready for immediate severance, before using the scissors in detaching the tongue from the floor of the mouth. The placed cord was not in my way at all in using the scissors; and its position, ready for immediate use, is obvious.—Yours faithfully,

June 1878.

W. FEARNLEY.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### ROYAL MEDICAL BENEVOLENT COLLEGE.

SIR.—The College election for 1877 over again. Yes, it is over, and after the old fashion: and with what results? It exhibits, firstly, more and more the indigence and penury of our hard-worked profession by the long list of candidates; and, secondly, more than ever the unjust, imperfect, and unreasonable carrying out of charity voting elections. If any one will take the trouble to analyse this list (even though they know no more than I do, which is nothing, personally, of the candidates), to what conclusion can he come but that the present system of voting is altogether wrong? Here is a list of thirty-nine candidates: eleven are elected—viz., one, first application: three, second; four, third; one, fourth; and two, fifth. The one at the head of the poll has polled between 2000 and 3000 more votes than two others who have stood five elections (though, truly, they are returned with him). But what has become of a third, who has now unsuccessfully stood five elections, being so short of advocates that in the five elections he managed to poll (each year's election being carried accumulatively) 1951 against the head or first applicant, and the only child of his father, or mother if you will—viz., 1812? Now, who can doubt the hardship upon these remaining applicants, especially those who have stood four, five, and even six elections? Each election, at the lowest average computation, must cost from £20 to £25. Hard, indeed, it must be upon the poor widow: 5000 stamps upon as many pitiful pleading letters will amount to £33.

But, alas! what more do we gather from this last election? Why, palpably that this top man is fortunate in having overwhelmingly the greatest number of friends; showing, in support of my oft-repeated communications in JOURNALS on the same subject, that it is not, it cannot be, the really truly indigent candidate that is returned, but those who, happily, have the longest list of friends; proving that the charity is at first eked out to these many friends, by which they are at once, without cost of a penny, released from the future care and education of their *protégé*; and probably a very large proportion of these supporters are well-to-do, seeing that they are, or should be, life or annual £2000 donors; and therefore it is I for ever will hold that these "well-to-do" folk should make way for the truly indigent candidate, who in his second canvass shall only poll 257. And in the obverse, if they really wish to be charitable, let these £500 and odd voters give 2s. 6d. per vote to their *protégé* call it the Archer fund if they will, by which they will provide in interest £40 or £50 *per annum*, sufficient to educate him at this first-class school, and at the end start him in life with the principal, or £1000 worth of half-crowns. This I should call charity in the right direction. As, however, I have intimated, I have written and said so much upon this matter, I can add no more: enough to say, I did not record one single vote at this last election, though having one hundred and fifty votes of my own; neither do I propose to do so till the present system of election be remodelled and put upon a sounder basis.

I still hold to my original suggestion, that a Committee in Council be appointed, and that they, and they only, be the parties to make out, by careful inquiry, the really most indigent and pitiable cases brought before them, and that no poor widow or friends shall be made to stand four, five, and even six elections before success. Neither should a candidate be kept in annual suspense, while he might be acquiring the benefit of education, instead of allowing new candidates to step in over him.

I beg you, sir, to pardon me this long communication. Let it be remembered that after this last election there are still left two "third applications", one "fourth", and one "fifth" for another contest, if the means be forthcoming; the remaining twenty-four as "first and second applications", the lowest on the poll being a second with 207 votes.—I have the honour to be, sir, your most obedient servant, East Rudham, June 10th, 1878. FRED. MANLY.

We are much obliged to Dr. Dickson (Constantinople) for kindly drawing our attention to the interesting pamphlet which he forwards, of which an early notice shall appear.

#### HIGH TEMPERATURE AFTER PARTURITION. WARBURG'S TINCTURE.

SIR.—If any person said this was not an age of progress in regard to medical science and the treatment of disease, we should be inclined to look upon such individual with a feeling of pity, and respond that rational therapeutics had not enlightened his mind, or set his mental faculties into good working order. The case recorded by Dr. Walker of Golcar, Huddersfield, on page 422 of the JOURNAL of to-day's date is one calling for some comment. When a patient in imminent danger recovers, we all feel gratified; but I am inclined to believe that upon many occasions we allow our feelings to be carried to an extraordinary length, and extol some agent which was employed in the cure of disease far above its merits or intrinsic value. I look upon Warburg's tincture in the above light, and think there is no reason for us to extol to the stars, and even beyond their immeasurable limits, any concoction of nearly a hundred ingredients, when a dose or two of quinine, the real "Warburg" ingredient, would have the same effect; and we should not enshroud medical men and patients' friends in some false mystery, and apply to Warburg's tincture a power which some other simple remedies are well known to possess. My object is to place before your readers something like a bird's eye view of the composition of the Warburg tincture, and leave my fellow-members to form their own conclusions. Many—especially the junior members of the profession—have never heard of some of the articles which enter into the composition of Warburg's tincture. I can only say it is composed of diverse, diverse, and adverse things, and is like the American quack doctor's black bottle, which contained a little of all medicines dispersed, and which was used as a *dernier resort* in difficult, obscure, and complicated cases. Such, then, is the celebrated "Warburg"; and I hope, for the honour and glory of the medical profession, we are not going to dabble in the hundred and one nostrums of our great great-grandfathers, and remake elixirs of fifty or sixty ingredients, which experience and common sense tell us are useless.

Now, Dr. Walker is, I think, astray in saying Dr. Broadbent published the formula for Warburg's tincture first. I use the word *first*, because the sentence leads one to infer that it was Dr. Broadbent. It was Dr. (Professor) Maclean of Netley to whom Warburg gave the formula, and Dr. Maclean published it in the *Lancet and Medical Times* of November 11th, 1875, in conjunction with a long letter. I do not wish to disparage Warburg's tincture, but here is the formula.

℞ Aloes (Socotri) libram; rad. rhei (East India), sem. angelicæ, confect. Damocritæ, ana uncias quatuor; rad. helenis (S. enule), croci sativi, sem. feniculi, cret. præparat., ana uncias duas; rad. gentiane, rad. zedoaræ, pip. cubebæ, myrrh. elect., camphor. e. boleti laticis, ana unciam.

The above ingredients to be digested with five hundred ounces of proof spirit in a water-bath for twelve hours; then expressed, and ten ounces of disphalpe of

quinine added; the mixture to be replaced in the water-bath till all the quinine is dissolved. The liquor, when cool, is to be filtered, and is then fit for use. Two drachms of such tincture would represent about three grains of quinine.

But now, what is the composition of confect. Damocritæ? According to one formula, forty-five ingredients enter into it, and the other gives forty-nine. A list of a few will show that it is composed of a little of everything, if I may use the expression: myrrh, saffron, agaric, ginger, cinnamon, spikenard, male frankincense, mithridate, mustard seed, opobalsam, coftus or zedoary, galbanum, castor, poley mountain, opium, red roses, asarum root, phu, bellies of skinks, honey, canary wine, dittany of Crete, Macedonian parsley seed, and a host of other things enter into it. Zedoary is the root of an Indian plant, which is somewhat aromatic and bitter, and angelica is a plant possessing aromatic properties, but a hundred years ago the seeds were thought to be inferior to the root. And such is the mysterious tincture—one which, I am certain, not a pharmacist in Europe would take the trouble to compound according to the old formula given for the preparation of some of its constituents. Many of the old articles of materia medica are not to be obtained.

In conclusion, I can only look upon the tincture as valuable simply on account of the quinine which it contains—about one grain in forty minims.—I am, etc., Northallerton, June 8th, 1878. HENRY BROWN.

SIR.—Allow me to rectify an error I inadvertently fell into in my recent communication. I find that Dr. Broadbent is quoting Professor Maclean in the article written by him in the *Practitioner* for February 1877; therefore, Dr. Maclean was the first to publish the formula for Warburg's tincture, Warburg himself having communicated it to Dr. Maclean. As I have received numerous inquiries by letter as to what Warburg's tincture is, I may add that full information is to be found in the article on Malarial Fever in Dr. Russell Reynolds's *System of Medicine*, or in the *Practitioner* for February 1877.—I am, etc., Golcar, Huddersfield, June 1878. J. BURNLEY WALKER, M.D.

DR. J. W. WATKINS (Newton-le-Willows).—Much as we regret it, we fear that the precedent desired would lead to inconvenient results.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Deabigh Herald; The Surrey Advertiser; The Stroud News; etc.

\* \* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

# THE HARVEIAN ORATION,

DELIVERED BEFORE  
THE ROYAL COLLEGE OF PHYSICIANS,  
Wednesday, June 26th, 1878.

By J. BURDON SANDERSON, M.D., LL.D., F.R.S.,  
Jodrell Professor of Physiology in University College; etc.

IN the deed by which Harvey provides for the delivery of the Harveian oration are set down three purposes which the orator was to place before him. One of these was that he should exhort the Fellows of the College to concord; the second, that he should call to mind our benefactors, and stir up others to follow their example; and, finally, that he should exhort the Fellows and Members of the College to study and search out the secrets of nature by way of experiment. As regards the first of these objects, the exhortation to concord, I have, I think, good reason for omitting it to-day—partly because I can offer no better motive to concord than that which Harvey himself offered, namely, that *concordiâ res parvæ crescunt, discordiâ magnæ dilabuntur*: but chiefly because we have so recently fulfilled in spirit another of Harvey's directions by partaking ourselves, and by inviting others like-minded, in reverence for Harvey's memory, to partake with us of a "feast of love and affection".

As regards our benefactors, I am required to mention them by name. I believe, however, that I shall sufficiently fulfil Harvey's wish if I name one benefactor who has recently aided us by the gift of a sum of money for the investigation of the nature and cure of Rabies and Hydrophobia. I do so not merely in expression of the gratitude which we all feel to Mr. Bennett-Stanford for his liberality, but in the hope that, to use Harvey's words, others may be led to imitate his good example. The investigation of so difficult a question must necessarily require the co-operation of many persons over long periods of time, but the object is well worthy of the liberality of enlightened and philanthropic men; for, although the number of sufferers from hydrophobia is small, there is none which is more formidable in its aspect; and, secondly, because there is good and reasonable ground for the expectation that the proposed inquiry, if undertaken in the right way and with sufficient means, will lead to valuable results as regards the prevention, if not the cure, of hydrophobia. If there ever were a disease to which the term "preventable" could be properly applied, it is hydrophobia. That efficient means have not before now been taken to prevent it is, no doubt, mainly attributable to the uncertainties which have existed as to its mode of origin; for in matters of prevention knowledge is power. Another reason why so little has been done may be that the number of cases of hydrophobia has hitherto been too inconsiderable to attract attention; but, now it has prevailed so extensively in Lancashire and the neighbouring counties, as well as in Somersetshire, that its elimination must be regarded as a matter of public interest.

And now let me pass on to the principal purpose of our meeting to-day, namely, that I should, to the best of my ability, exhort the Fellows and Members of the College "TO SEARCH AND STUDY OUT THE SECRETS OF NATURE BY WAY OF EXPERIMENT".

We have heard so lately from the eloquent lips of Mr. Huxley, as well as on former occasions like the present from Harveian orators more capable than myself, in what the merits of Harvey as a discoverer consisted, that I may venture to take for granted that all my hearers are already conversant with his life and work, and am the more willing to do so that there seems no reason to believe that Harvey intended that his own achievements should form any part of the subject of the oration which he instituted. What we have to-day to consider is, not what he did, but how to follow his example. It is as our example, therefore, that I shall speak of him. For he deserves our gratitude, even more than for the discovery itself, for this: that, in his investigation of the circular motion of the blood, he gave his successors a model of the method by which all discoveries in physiology and in pathology have been made since. The essence of that method is expressed by him in the one word—experiment.

In these memorable words of Harvey, Nature is presented to us, not as an arrangement of objects in a museum for our contemplation, but under the figure of a living personality, of whose unceasing activity we and all other creatures are the expressions, and whose will is opposed to our efforts. Nature has secrets which she desires to conceal from

us; her whole proceedings, indeed, are so recondite that the naturalist who contents himself with the mere contemplative study of her external aspects is, unless he wisely abstain from all attempts to interpret what he sees, more likely to fall into mistakes than to arrive at just conclusions—a fact which was expressed by Hippocrates in his often misquoted words *experientia fallax*. The idea which is expressed in the words of the injunction is that of struggle, of striving for the mastery. Nature on her part is at work on all sides of us, and desires to conceal from us her operations. We, on our parts, by virtue of the faculties with which she has herself endowed us, have the power, and along with the power the right and the duty to wring from her her secrets, as it were by force. Unquestionably there never was a more splendid exemplification of this struggle with Nature, than is afforded in the history Harvey has himself given us of the discovery of the circulation.

Actuated by that insatiable curiosity, that lust for knowledge of the unknown, which is the essential characteristic of the naturalist, not being satisfied with what he could learn of the motions of the heart and arteries by contemplation of the external phenomena of the circulation, or with any conjectures which he could draw from his very complete anatomical knowledge of the structure of the heart and blood-vessels, he had the boldness to open the chest of a living animal, to inspect the motions of the living heart, to feel with his own hands how it hardened in contraction and grew soft in diastole; to observe what happened when, by ligaturing the aorta, he prevented it from discharging its contents, or when, by similarly occluding its afferent veins, he deprived it of its supply of blood; his purpose in all these experiments being, not to verify a preconceived inference, but simply to strip nature of her concealments, and to force her, thus exposed to the light of day, to reveal her own secrets in language so plain, that it needed no interpretation, so convincing that, to those who believed the evidence of their senses, it required no enforcement by argument.

And here let me notice that Harvey has been represented by many of his most ardent admirers as much more of a reasoner and much less of an observer than he really was, and that some have been thus led to a mistaken view of his method. The discovery of the circulation may, in a certain sense, be truly described as "one of the most admirable and useful inferences ever given to the world"; but no one who had realised the nature of the moral and physical difficulties which Harvey had to overcome would so characterise it.

As a true interpreter of phenomena which his predecessors had seen but misunderstood, Harvey is worthy of all honour, nor will anyone who has attentively studied his writings, particularly the treatise *De Motu Cordis*, be disposed to underrate his power in this respect. But the essence of his achievement was, that he saw and felt for himself the motions of the heart and arteries, and displayed and demonstrated them to others in such a way that their meaning could not be misunderstood, nor their truth disputed. It was the certainty of the facts and the simplicity of the language they spoke that constituted the greatness of the discovery.

In the present lecture, I propose to illustrate, by reference to the history of some of the investigations which have served as the foundation of so much of our present knowledge in relation to the circular motion of the blood as was concealed from Harvey, the methods by which now, as in Harvey's day, all natural knowledge is acquired, and then to offer practical suggestions for the guidance of those who, being like minded with Harvey, desire to fulfil its injunctions and to follow his example.

The shortness of the time at my disposal compels me to limit myself to one subject; namely, to the researches by which, in the first half of the present century, the Harveian doctrine of the working of the circulatory apparatus was developed. I had intended to give some account of the still more important discoveries of the last thirty years, but have found it impossible. It is satisfactory to reflect that England, which gave birth to the author of the doctrine of the circulation, was also the country of the two men (living at intervals of a century from each other, and the first of them a century after Harvey) who, in great measure, completed it. Stephen Hales, a Doctor of Divinity and a benefited clergyman of the English Church, was an active member of the Royal Society when Sir Isaac Newton was President, a contemporary of Locke, of Cheselden, and of the anatomist Cowper. Hales was a genuine naturalist. His writings afford evidence that he was a firm believer in the religion of which he was the minister: but in matters of science he was a sceptic, accepting nothing short of "the united testimony of many good and credible experiments" as the foundation of knowledge. He was no less distinguished for his physical than for his biological experiments, most of which were undertaken for useful purposes (as, for example, those relating to the distillation of sea-water for ships, and those on the preparation of salt provision); but others, in the conviction that "the obtaining a better insight into

the nature of plants or animals would improve the arts of medicine and agriculture\*.

The purpose of Dr. Hales's experiments was to measure the force and velocity of the circulating blood, and to obtain thereby data, as he expresses it, "on which to found just calculations". In planning his experiments, he was guided by as clear a comprehension of the relation between physical laws and vital phenomena as he could have possessed had he lived a century later. Inasmuch, he says, as "the animal fluids move by the same hydraulic and hydrostatical laws as those which prevail outside of the body", they must be investigated by the same methods of mensuration. Hence, if we compare his work with the best researches of the present epoch, the difference is found to consist only in the comparative incompleteness of his appliances; for his experiments on animals, although made by what we should call rough methods, were yet right in principle, were carried out with great care, and were frequently repeated under varied conditions. Hence his results, although they have been vastly amplified, have needed no correction. In this way, Hales acquired a title to the highest commendation that can be bestowed on a naturalist; he made no mistakes of observation; but it was also true that he made few errors of inference; for, while recognising that "from conjecture fresh discoveries take their rise", he was yet content "to imitate children who, for want of better skill and abilities, and of more proper materials, amuse themselves with slight buildings".\* In point of fact, he did not extend his inferences so far as he might have done, leaving it, as we shall see, to another to give the full interpretation of his observations.

Dr. Hales had no immediate followers, nor did either of the three great physiologists of the eighteenth century—Haller, Spallanzani, and John Hunter—add materially to the knowledge which Hales gained by experiment as to the motion of the blood and its causes. As regards Hunter, indeed, it must be admitted that the doctrine of the "action of the arteries", to which he was led by his pathological researches, was a step in the wrong direction, though it might be shown that it contained the forecast of a great truth.

The next step was accomplished eighty years after Hales's discoveries had been communicated to the Royal Society, by a man who, though a distinguished Fellow of this College and an eminent physician, was a much greater mathematician and physicist. Dr. Thomas Young, to whose transcendent merits in the more exact department of natural science full justice has been done by his successors in the same lines of inquiry, was as far in advance of the other men of his time in physiology as he was in natural philosophy. That he was so must be attributed principally to his extraordinary intellectual powers—powers which, even in early youth, made him a prodigy of erudition in spite of great disadvantages of education; so that, at the age of eighteen, he had acquired such proficiency in the classical languages that, as Dr. Peacock says, he was already prepared, on questions of Greek criticism, to enter the lists with the most distinguished scholars of his time. That even at this early period his attainments in mathematics and natural philosophy must have been equally remarkable, we have evidence in the facts that he was only twenty when he offered to the Royal Society the paper (on the Mechanism of Accommodation) which procured him the honour of its Fellowship; and that he was only twenty-seven years old when he made the first of that series of investigations relating to the interference of sound and of light which have placed him, to quote from Sir John Herschel, in the "highest rank of scientific immortality". The same year that he became Fellow of the Royal Society, he entered as a student of St. Bartholomew's Hospital. Afterwards he went to Edinburgh, and thence to Göttingen, whence, like Harvey, he returned in due time to graduate in medicine at Cambridge.

In order that we may be in a position to discuss Dr. Young's researches as to the mechanism of the circulation, let me define the limits of the existing knowledge of the subject at the time when that he undertook them. As regards the fundamental facts of the circulation—viz., that every particle of blood which leaves the heart by the aorta comes back to its starting-point—Harvey's knowledge was, I need not say here, as nearly as possible complete, the only gap being that he was unacquainted with the nature of the channels by which the smaller arteries discharge themselves into the veins—a blank soon to be filled up by Malpighi. The gap was a very trifling one indeed; but Harvey deliberately avoided supplying the missing link by conjecture or inference, leaving the question of the channels of communication between arteries and veins entirely open. As regards the cause of the motion of the blood, Harvey's knowledge was also wonderfully complete; but there was one deficiency. There is evidence in his works that he knew much more clearly than many subsequent writers that the force

by which the blood is impelled along the arteries is a muscular one, and that the heart in its systole grasps and squeezes out its contents. All this is perfectly clear; but it is no less certain that he did not know what was the cause of the venous blood-stream. The explanation which he gives for the return of the blood from the periphery to the centre is very much this: the blood spontaneously inclines from the circumference to the centre, just as drops of water spilt upon a table concentrate to the mass of liquid. Consequently, although the progress of the blood "from the capillary veins to the larger trunks is aided by the compression of the muscles", it has an innate tendency of its own towards the heart, which, when it reaches, it becomes attenuated by its increasing heat so as to dilate the right auricle. It would be, I think, a mistake to allow our admiration for his intellectual character to blind us to the fact that in these passages\* Harvey yielded to a tendency against which I do not think we have any need to guard ourselves at the present moment—a too great reverence for antiquity. The doctrines of diastole by innate heat or fermentation, and that of the innate tendency of the blood to return from the periphery to the heart, cannot be regarded as expressing inferences which he had himself made. But they are of interest, as proofs that he did not clearly understand what was the real cause of the venous blood-stream.

The proof that the flow of blood throughout the whole vascular system is dependent on one and the same cause as the arterial blood-stream—viz., on the difference of pressure between the arterial and venous ends of the system of tubes which constitutes the vascular apparatus—was really contained in the experiments of Hales; but it required the application of the trained mind of Dr. Young, a mind trained in the image of Newton, to expound and develop it. The principle of Hales, that the animal fluids move by hydrostatical laws, which, *mutatis mutandis*, we now accept in its applicability not only to the phenomena of the circulation, but to every other function of the animal body, was enunciated by Dr. Young in the opening paragraph of his Croonian Lecture,† in the following memorable words: "The mechanical motions, which take place in an animal body, are regulated by the same general laws as the motions of inanimate bodies. Thus the force of gravitation acts precisely in the same manner, and in the same degree, on living as on dead matter; the laws of optics are most accurately observed by all the refractive substances belonging to the eye. . . . As far, therefore, as the functions of animal life depend on the locomotions of the solids or fluids, those functions must be capable of being illustrated by the consideration of the mechanical laws of moving bodies; these laws being fully adequate to the explanation of the connection between the motive powers, which are employed in the system, and the immediate effects, which they are capable of producing, in the solids or fluids of the body; and it is obvious, that the inquiry, in what manner, and in what degree, the circulation of the blood depends on the muscular and elastic powers of the heart and of the arteries, supposing the nature of those powers to be known, must become simply a question belonging to the most refined departments of the theory of hydraulics."

Dr. Young had already communicated to the Royal Society a remarkable series of physical researches as to the motion of liquids in rigid and elastic tubes—researches which still constitute the basis of our knowledge on that subject. The purpose of the Croonian Lecture was to combine the results of his own investigations of the motion of liquids in elastic tubes with the measurements of Hales as to the arterial pressure and the velocity of the blood-stream in living animals; and on this double foundation of physiological and physical experiment to construct a true doctrine of the motion of the blood in the vascular system. In this purpose he succeeded. The most important result of his investigation being to show that everywhere, whether in arteries, capillaries, or veins, the blood moves forward with a velocity which is directly proportional to the difference of pressure, and inversely to the resistance to be overcome; and, secondly, that inasmuch as the pressure in the smallest arteries is less by only a fraction than the pressure in the aorta itself, the force which is still available at the commencement of the capillary circulation is nearly equal to the total force which is engaged in carrying on the circulation. It thus became evident that the difficulty which Harvey had had in understanding how it is that the blood returns from the peripheral parts to the heart (a difficulty which no physiologist, not even Hales, since his time had explained) arose merely from the circumstance that the laws which regulate the motions of liquids in tubular channels had not been investigated, and therefore could not be applied.

With reference to these inquiries of Dr. Young, there are two things worthy of notice; namely: first, that, being content with the data furnished by the measurements of Hales, he made no physiological experi-

\* See Harvey's *Works* (Sydenham Society's edition), pp. 70 and 133.

† The Croonian Lecture "On the Functions of the Heart and Arteries", by Thomas Young, M.D. (*Philosophical Transactions*, 1809, pt. i).

\* Preface to Hales's *Hæmstatics*, page 6.

ments himself; and secondly, that although his exposition of the theory of the motion of the blood was perfectly clear, and—supposing the data to be correct—absolutely conclusive, it had little or no influence on the teaching of physiology at the time; the general doctrine being that the motion of the blood was not regulated by the same laws as the motions of inanimate liquids, and, in particular, that the blood-stream in the capillary blood-vessels was aided either by what was called the *vis insita* of the blood itself—a mysterious tendency on the part of the blood to move onwards (as Kaltenbrunner supposed)—or to an equally mysterious vital attraction between the walls of the capillaries and their contents, the doctrine first advanced by Bichat. Possibly, if it had not happened that Young was engrossed in the prosecution of those more brilliant investigations which have made his name famous, it might have been otherwise. The reason of this want of influence is to be sought chiefly in the fact that the time for the development of physiology as a science dependent on measurement—that is, as a branch of physics or natural philosophy—had not yet come; for although, as regards the particular case of the circulation, the facts had been observed with sufficient exactitude and completeness to admit of the application to them of theoretical treatment, yet in almost every other direction this was rendered impossible from the absence of physiological data, and the insufficiency of the means which then existed for obtaining them.

It must not, however, be supposed that Young's work was lost, though at the time it appeared so fruitless. Just as his two most important discoveries in optics and acoustics have, during the last thirty years, been developed by Helmholtz, so in like manner his work regarding the motion of the blood has been continued and completed by the veteran physiologist, or rather physiologist and anatomist all in one, whose loss science has had to deplore during the current year.

Ernest Heinrich Weber, who was in many respects a man to be placed side by side with Young, entered on the study of medicine the very year that Young read his famous Croonian lecture. He began his career as a comparative anatomist, and had already achieved so great a reputation as to have become professor in the University of Leipzig, when he undertook those physical experiments relating to wave-motion, by which perhaps he is better known than by his anatomical discoveries. It seems that he was guided thereto partly by accident, for we are told that he was first led to the investigation of wave motion by the observation of the surface-undulations of the mercury which he used for his anatomical injections. But here, as in other instances, it was the character and training of the mind that received it that gave to the suggestion its value. Weber was a mathematician and physicist, and had already worked with Chladni at his well known researches on sound. The *Wellentheorie* appeared in 1825, and was soon followed by a dissertation in Latin on the arterial pulse. In this dissertation he showed, by the same methods which Young had applied to the progressive motion of the blood, namely, by combining physical with physiological experiments, the complete identity of the laws which regulate arterial pulsations with those which govern the propagation of pulsations in elastic tubes. The results of Weber's researches on the physics of the circulation were finally, in 1851, embodied in a treatise in which he established the science of hæmodynamics on the solid basis of exact measurement.

And now we have arrived at the middle of the present century, the threshold of a new epoch, differing from that of Harvey in consisting not of one discovery but of a rapid succession of them, agreeing with it, however, in deriving its importance quite as much from the complete revolution in the methods of investigation which marked it, and in the reconstruction of the science which has resulted from that change, as from the discoveries themselves.

We have already seen that Harvey's method was to strip Nature of her concealments, and thus force her, as it were, to reveal her own secrets. During the next century after Harvey, the same simple method of exploration was followed by Haller and Spallanzani; and in the present century by Magendie, all of whom were distinguished by the same wise scepticism, the same love of objective truth, that enabled Harvey to conquer the spirit of his time, even in his own person. But just as it happens in agriculture, that the rougher methods of tillage, which at first are found to be sufficient to produce abundant crops from the virgin soil, become later unavailing, and have to give place to others more systematic and refined; or, as in warfare, every improvement in the methods of defence necessitates a corresponding improvement in those of attack, so it has been in scientific investigation, and particularly in physiology.

By the time that Magendie wrote his celebrated *Compendium*, almost all that could be arrived at by the rougher modes of observation—the method which consisted in removing the veil from the hidden motions of the organism and exposing them to the scrutiny of the unaided

senses—had been already attained, and it was necessary to have recourse to more elaborate and more systematised methods of attack. But for this a leader was needful,—a generaliser even more than an explorer. Such an one soon presented himself in the person of Johannes Müller, a man of similar power to Young, with this important difference, that he was a consummate anatomist and morphologist, and combined therewith so considerable an acquaintance with the physics and chemistry of his time that he was able to grasp the whole range of physiological knowledge as completely as Young did the few subjects to which he exclusively directed his attention. As a mere investigator, he illuminated many obscure regions, as, for example, those relating to the specific endowments of nerves, and to the mechanism of voice and hearing; but it was not merely as a searcher, in the Harveian sense, that he has the chief claim to consideration. The great service that he rendered to physiology was that by the universality of his knowledge and by his power of separating the true from the false in observation and experience, he was able to bring together all that was known as to the chemical and mechanical processes of the body into a system, and thus to lay the foundation on which his pupils—Helmholtz, Brücke, Ludwig, Du Bois-Reymond, Max Schultze, Virchow—and their followers, during the last thirty years, have reared that newly constructed branch of natural science which we now understand by the word physiology.

The necessity for this reconstruction of physiology as a new science, on a new foundation, with new materials, became evident as soon as physics and chemistry were sufficiently advanced to furnish exact methods for the investigation, not merely of such comparatively simple questions as the mechanism of the circulation, but also of the more complicated ones relating to muscular contraction, to the transmission of molecular changes in nerves, to the chemical process of respiration. Thus, in the case of the last-mentioned function, the moment that it was seen that the actual relations of oxygen and carbonic acid in the tissues were entirely inconsistent with notions founded on previous observations—which though correctly made were made with insufficient methods—it became evident that the whole of the facts must be re-examined, whether actually proved to be incorrect or not, by comparison with standards of absolute certainty. For similar reasons, the experimental results of Magnus on the chemistry of respiration, of Matteucci on animal electricity, of Young on the mechanism of accommodation, and many others, have been compelled to give way to new ones, not because these great men made mistakes, but simply because other men, perhaps not so great as they, equally conscientious and trustworthy, and furnished with better appliances, have gone over the same ground and have obtained data which are not only more complete and comprehensive, but possess, so far as they are based upon measurement, an element of permanency which was wanting in those they have supplanted. Thus the modern physiologist aims at presenting, not his perception of a form or of a motion, but the result of his comparison of that form or motion with an invariable standard; and it is this which mainly constitutes the difference between his method and that of his predecessors. The process of investigation consists now as ever in searching out the secrets of Nature by experiment, but the experiments of modern physiology are much more difficult, require for their performance more previous training, quite as much devotion and self-denial on the part of those who engage in them, more combination of individuals of different capacities for the attainment of one result, and consequently more money and more time.

Nothing could be more interesting, had I the ability or the time to do it, than to trace in broad outline the progress of the great revolution of which I have endeavoured to indicate the nature.

But time warns me that the most important duty of the day still remains unfulfilled; namely, that we should endeavour (partially and incompletely it must necessarily be) to consider how best to follow Harvey's example. In all that I shall say on this subject, I must ask to be understood to address myself to those who are in the enviable position of being the youngest members of the College. For us, if we have not already learnt the lesson conveyed to us in our motto, it is too late to learn it now. But for those who have still the best of their lives before them the choice is open.

If research is to be done at all, it must be begun in the morning of life. One reason of this is the internal condition of intellectual fitness: the other the external one of leisure. Of the first I need say little. It can scarcely be questioned that it is in early maturity that the mind is most capable of the continuous struggle of which, as we have seen, research consists. For those qualities of mind which specially belong to the naturalist—the lust of knowledge, the love of truth, and the joy of successful effort—are apt to lose their power over us as life advances. As a rule, therefore, we should begin to work early, and work while it is day, for the night cometh, when no man can work.

As regards leisure, it is, I believe, the result of general experience, that a man who aims at the high professional position occupied by the Fellows of this College may reckon on ten or twelve years which are, for the most part, at his own disposal. How may these years be used as Harvey would have used them?

Harvey began his active career as a physician in 1609, and probably very shortly afterwards became engaged in lucrative practice. He left Cambridge, where he was educated, in 1597, spending the next six years of his life at Padua, and returning to the university to graduate as Doctor of Medicine in 1603. If, therefore, we reckon his mature life to have commenced from his bachelor's degree at Cambridge, he enjoyed at most eight years of freedom from business. Of these eight years, the first five were spent at Padua; and these, in relation to Harvey's development as a discoverer, must be regarded, with reference to their future influence, as among the most important of his life. For during his residence at Padua he was under the influence of the man whom he calls "foremost among the moderns", and places side by side with Aristotle. As to his mode of student-life in Italy we know nothing; but we may be sure that he worked very earnestly under the guidance of Fabricius, particularly at those anatomical researches relating to the formation of the chick which were afterwards to be the point of departure in his inquiries respecting generation. Had Harvey not gone to Padua, he might have been a favoured courtier, a successful physician, an influential citizen—all, in fact, that he actually became—but not the discoverer of the circular motion of the blood.

If we now compare Harvey's use of his leisure with that which is possible to the modern physician, we shall find contrasts which may suggest useful considerations. And, first of all, it is to be noticed that the conditions of modern professional life in London have deprived these first decades of much of their value; for in London, long before a man becomes occupied with patients, he ceases to be master of his time. I need scarcely say that I do not refer to the social engagements of London life, but to occupations of a more serious and less agreeable character—to the wearisome labour of the out-patient room, to the unattractive duty of systematically teaching some subject in which the teacher has no special interest, or, finally, to the literary labours which most men find it necessary to impose upon themselves—engagements which are all of such a nature as to render impossible that earnest and continuous devotion of time and energy to real study which is the first and preliminary condition of success in investigation.

Another contrast between the conditions under which Harvey lived and worked and those of the present moment relates more particularly to his life at Padua before his medical graduation. It is scarcely possible to imagine intellectual conditions more entirely different than the free converse which Harvey enjoyed with such a man as Fabricius, and the strictly regulated studies of an aspirant to the doctorate of the University of London; and out of the comparison arises the question, Which of the two is preferable? The advantage is not so entirely on the side of the modern method of training as it might at first sight appear; for, although it may be in some respects more useful that a man should be conversant with all branches of medical science than that he should be master of one or two, it is not the less certain that for the purpose which we have to-day in view—that of fitting a man for the searching out the secrets of Nature by experiment—that sort of encyclopædic knowledge which he acquires in order to prepare himself for the examiner is of little or no value.

In order to form a just conclusion on this subject, we cannot do better than follow the principle laid down by Harvey in his introductory essay *On the Manner and Order of acquiring Knowledge*, in which he says that no one can properly become a student of any branch of natural science until he is able to rely on his own observations and not on the observations of others. Now it is evident that this does not apply to the mere disciple in natural knowledge, who, so long as the *status pupillaris* lasts, must rely on the experience and knowledge of others. It begins to apply from the moment that the transition takes place from discipleship to studentship; and what we have to guard against in the interests of science—which I regard as identical with those of real study—is, that this transition, this liberation of the student, should not be too long deferred. Harvey was freed from academical restrictions at the age of twenty, when he went to Padua; Young left Edinburgh for Göttingen at the age of twenty-one. In London, a man graduates as Bachelor of Medicine at soonest at twenty-three. But, unfortunately, he does not yet enjoy that intellectual freedom which is one of the essential conditions for genuine and productive intellectual works. Does any one doubt that the undue prolongation of the bondage of examinations is a serious evil? Is it too much to hope that the University of London, to whom we owe the establishment of the important principle that scientific training is a necessary preparation for the study of medicine, will some day recognise that she

has still higher functions to perform, and that she has it in her power by bestowing her most valued rewards, not on proficients in the examination room, but on students in the Harveian sense; that is to say, on men distinguished for attainments in some branch of medical research, to do a far greater work than she has yet done for the advancement of medicine?

Having thus endeavoured to illustrate by antithesis the external conditions which I regard as essential to the development of a student after Harvey's model, namely, that he should enjoy sufficiently early in life leisure for real study, and perfect freedom in the choice of subjects and methods, allow me to say a word as to what I believe to be one of the best means of using it. Up to a comparatively late period, it was a common practice for men who aspired to the higher ranks of the medical profession to go abroad at the close of the curriculum. Now, partly owing to the external conditions to which I have already alluded, that is, to the absorption of time and intellectual energy in the work of preparing to meet the examiner, and partly, no doubt, to the improvement of the means of study which offer themselves in London and elsewhere in this country, the custom has been in great measure discontinued. I confess that it seems to me that in this respect our predecessors were more judicious than we are ourselves. If a man's whole object be to furnish himself with the skill and knowledge needful for the efficient exercise of his profession, the schools of London will afford him everything that he can require for the purpose. But it is not about technical training that I am speaking, but research; and, if that be his object, a man cannot do better than take Harvey as his example in this as in more important matters.

Harvey went to Padua, not so much to learn the medical or surgical art, but to study anatomy, the only representative at that time of medical science. He who desires to prosecute those branches of research on which medicine is now founded, can find quite as solid reasons for visiting the schools of Germany now, as Harvey had for going to Italy. What those inducements are, can be stated in few words. It is not merely because the imitation of Harvey is denounced by public opinion and impeded by legislation, that it is desirable that he should cross the Channel, but rather that during the last twenty or thirty years we in England have, like the foolish virgins, been quietly allowing our lamps to go out. While we have been contenting ourselves with putting up statues to Harvey, dining in his honour, recounting his great achievements, we have handed over to others the doing of his work. Until, therefore, England again takes the place that formerly belonged to her in physiological research, those who desire to devote some part of their life to searching and studying out the secrets of nature, will act wisely in so arranging their plans of study, that some years may be spent in the schools of other countries, where, along with leisure for work, they will derive advantages of the same kind with those that Harvey did from his residence at Padua—the co-operation and guidance of the very men to whom the sciences they profess owe their present development.

And let me add that all that has been said as to the study which Harvey had directly in view in the injunction which has served as the text for this address, applies with equal, if not greater, force to those branches of physiology which are more directly connected with the art of medicine.

Germany, recognising that the progress of the art of healing depends as certainly, though not so directly, on science as the art of war, has erected during the last ten years in all the great centres of medical learning specially endowed institutions or schools for the experimental study of those two sciences, which together make up the one science of medicine: namely, Pathology, the knowledge of the cause and nature of diseases; and Pharmacology, the knowledge of the mode of action of remedies.

How does it happen that we in England, who boast of being the countrymen of Bacon, of Harvey, of John Hunter, and of Charles Bell, and who believe that we know better than others the practical value of knowledge, whose material resources surpass those of every other nation, and who in certain favoured directions are willing to spend public money for purposes supposed to be scientific with lavish prodigality, should make no provision whatever, either in our universities or in our magnificently endowed schools of medicine, for the prosecution of experimental research either in pathology or in therapeutics? The question admits of but one answer, namely, that the time has not yet come. Sooner or later—perhaps twenty years hence—it will certainly be recognised that the scientific investigation of the essential nature and origin of disease and of the mode of action of remedies is a matter of no less importance to the public welfare than the application of the sciences of physics and chemistry to the invention of new methods of destroying human life.

## LECTURES

ON THE

DIAGNOSIS AND SURGICAL TREATMENT  
OF ABDOMINAL TUMOURS.*Delivered at the Royal College of Surgeons of England.*

BY

T. SPENCER WELLS, F.R.C.S.,

Professor of Surgery and Pathology in the College; and Consulting Surgeon to the Samaritan Hospital.

LECTURE III—*June 14th, 1878.**Surgical Treatment of Ovarian Cysts and Tumours; Tapping, by Abdominal Wall, Vagina, or Rectum; Tapping, with Drainage; Injection of Iodine, or Antiseptics; Incision and Drainage; Ovariectomy—Selection of Cases—Preparation of Patient—Instruments—Anesthetics; Duties of Assistants and Nurses.*

I AM about to commence to-day by considering the question of the surgical treatment of ovarian cysts and tumours. I will begin with the treatment by tapping. There is still a great deal of difference of opinion amongst surgeons as to the amount of danger that attends tapping, and the amount of good that may be gained by it. I think the opinion of the profession is almost as unsettled now as it was when Stilling wrote, some years ago, in his paper upon the extraperitoneal method in ovariectomy, that "no surgeon should ever puncture an ovarian cyst". Tapping, he said, was a "crime"—"never tap". And the belief is general, that ovariectomy is rendered more dangerous when a patient has been tapped. There are still surgeons who entertain that belief; they object to tapping on two grounds: first, that it is dangerous in itself; and next, that it can only be of temporary use; and then, again, they fear that it is likely to be followed by adhesions or some other conditions, which very greatly add to the danger of ovariectomy when it is afterwards performed. With regard to the amount of danger in tapping, it seems to me many of the opponents of this simple proceeding fall into a considerable error in attributing to tapping what ought to be considered as due to the disease. If a patient die after tapping, she does not die because she is tapped; she dies because the tapping does not save her life. She would die if left alone, and tapping gives her relief for a time; the cyst fills up again, again requires tapping, and after one or more tapplings she dies. It is not the tapping that kills her; she dies because the tapping does not save her. I fancy if we make a clear distinction between operations that fail to save life and operations that kill patients, we shall make a distinction between tapping as a mode of relieving for a time a patient suffering from an ovarian cyst and ovariectomy, which if it do not succeed in saving life, kills the patient.

It is very seldom indeed that tapping is in itself dangerous. Occasionally, a blood-vessel in the abdominal wall, or in the cyst-wall, or in the omentum, may be wounded, and the patient may die of bleeding; but that is the rare exception to the general rule, that tapping is attended with very little danger. A greater danger than bleeding is when air enters the cyst, and with the air some elements of putrefaction; putrefactive changes are set up in the fluid still contained in the cyst, or which re-forms after the tapping, and then the patient dies from some form of pyæmic fever or septicæmia. That may be now looked upon as the chief danger after tapping; and it may hereafter probably be lessened or averted altogether by the adoption of antiseptic measures.

With regard to the mode of tapping, it may be done either through the abdominal wall, the vagina, or the rectum; and in either case, we may trust to tapping alone, or to tapping followed by pressure; the punctured opening may be allowed to heal, or the opening may be kept patent by some form of drainage-tube, in the hope that a cure may be obtained by a more or less permanent drainage of the cavity; and with this drainage there may be associated the injection of iodine or some antiseptic fluid. There was a proposal at one time made which has not been very frequently followed, that of purposely leaving the opening in the cyst-wall patent, so that the fluid as it formed

might gradually escape into the peritoneal cavity and be absorbed, producing pretty much the effect of a ruptured cyst.

When tapping through the abdominal wall was performed in the early days, it was done with the patient seated on a chair, an assistant on each side of the patient, a long towel fastened round her, possibly an opening in front of the towel, a pillow was placed between the patient's legs, and then the surgeon, taking one of these old-fashioned trocars, with considerable force plunged it into the abdomen. Sometimes a small incision was first made in the skin with a scalpel or lancet, in order to lessen the force necessary to pass the trocar inwards. But it was very soon apparent that the danger which followed tapping in this way was due a good deal, in the first place, to the position of the patient, and, in the next, to the instrument used. The fainting of the patient, even notwithstanding firm compression by bandages or towels, almost necessarily due to the upright position, could be avoided altogether by having the patient in a recumbent position, not taking her out of bed, simply bringing her to the edge of the bed lying on her side, and tapping in that position. In that way, no bandages were necessary, and a very large cyst might be emptied without any faintness being felt by the patient. In some cases, the surgeon would tap a patient with a trocar, and it would be what Sir Astley Cooper called "dry tapping"—no fluid followed. That arose from shortness of the cannula in patients having a thick abdominal wall. I suppose this trocar would hardly go through the abdominal wall of a patient having an inch or an inch and a half of fat; by the time it reached the cyst it would barely enter it; and then, when the trocar was withdrawn, the fluid, instead of passing through the cannula, escaped into the peritoneal cavity. Again, supposing one did with a trocar of this kind enter the cyst, and removed the trocar, leaving the cannula in the cyst, after a certain amount of fluid had escaped, the cyst contracted and fell off and sank into the peritoneum, so that no more fluid escaped, or it came away only gradually. I have seen all these things occur myself; and the first thing I did in altering the old instrument was to increase the length of the cannula; and by simply lengthening the cannula I avoided both the danger of not opening the cyst, and that of the cyst falling off the cannula. Then Mr. Thompson of Westerham made the great improvement, of which there is an exaggerated specimen here. He arranged the trocar in such a manner that, when it entered the cyst, the trocar was withdrawn beyond the point at which the fluid escaped down the long flexible tube; he thus effectually prevented any danger of air entering from the outside into the interior. He took a great deal of trouble to do this by putting the tube into a vessel of water, sucking at one end until the water rushed up through the tube. By advancing the trocar, he kept the tube full of water, and as the lower end was under water in the pail beside the bed, of course no air could come up and get into the cavity of the cyst when the piston was withdrawn. I soon found that filling the tube with water was quite unnecessary, because it was only a question of the level at which one passed the trocar into the cyst. But there were one or two objections to this instrument. In the first place, there is a little interval of time—a moment—between the entrance of the point into the cyst and the withdrawal of it, in which instant there may very possibly be some escape of fluid between the sides of the cannula and the punctured cyst. I have seen that occur in ovariectomy, and I have no doubt it occurs also in ordinary tapping; so that I was anxious to avoid that moment which is lost between the entrance of the trocar and the removal of the piston leaving the cannula free. It occurred to me that a common steel-pointed pen would do as well as anything; and I thought if that were passed into the cyst, the fluid would run freely away, and it would be easy to make a syphon trocar. After a little trouble, my suggestion was carried out, and the instrument I now show was the result of that trial, and it is the one which I have used ever since. The point is exactly like the point of a steel pen, and is so made that it does not cut a piece out of the abdominal wall, but simply enlarges the opening made by the scalpel. A small opening is made first by a lancet or scalpel, and then this instrument is easily passed into the cyst. It is evident that, if this were left in the cyst, it would be dangerous when the cyst was empty; a sharp point like this in the interior of a contracting cyst would be pretty certain to wound it; so I added a blunt cannula. I first put the cutting point inside, but afterwards found it better to slip up the blunt cannula inside the sharp tube, and that is the form of instrument now used, passing with the point directed downwards, so as to avoid any rush upwards of air which might occur if the point were at a higher level than the end of the tube. With the tube, the instrument at once becomes a syphon, and this calibre is large enough to allow the escape of viscid fluid. There are several small openings in the cannula; because, if one opening be too large, there is the possibility of the entrance of little bits of omentum or small shreds or clots, which may be in the interior

of the cyst. These would block the tube; therefore it does not do to make one opening too large. By fixing a long elastic tube on to the end of this instrument, the fluid is carried silently away into a vessel under the bed; the patient does not hear any splashing, and there is no possibility of any air entering into the cyst. Supposing the fluid—whether peritoneal or cystic—is in the peritoneal cavity, or there is a doubt as to where it is, it is desirable to remove such fluid without the possibility of wounding any uterine tumour, or any mass of cancer, or injuring the intestines or omentum. For this operation I contrived this form of blunt conical cannula, which is used after a simple lancet-puncture. On passing a lancet or small scalpel through the abdominal wall until fluid appears, then removing the knife and pushing this hollow tube into the cavity, the fluid at once rushes away. The tube may be moved about as a probe to feel whether any tumour is free or adhering, and we can do that without the slightest fear of doing any harm. With these several small openings, there is no fear of portions of omentum becoming entangled by the pretty strong suction that goes on through the long syphon.

There have been one or two modifications made in this instrument. Here is one by Dr. Fitch of New York, and he believes the form of protector is of some little consequence. He calls his the "dome-shaped" trocar. It is precisely the same as mine, except that the guard is made in a dome shape. It is quite easy, supposing one wishes to wash out a cyst, to fix an ordinary enema-syringe to the end of the elastic tube, and either to exert suction on the fluid contained in the cyst, or to inject any antiseptic liquid, and draw it out again by reversing the action of the syringe.

Tapping through the abdominal wall in some cases becomes not only a means of temporary relief, but if the cyst be really a single cyst it may be followed by the complete cure or recovery of the patient. I have known, now, a great many cases where, when the cyst proved to be really single or unilocular, it never refilled after the first tapping: the patient was by this very simple means completely cured. So I think we may lay down almost a positive rule, that, when we can be sure that the cyst is a single cyst, and we cannot discover any secondary growths in the cyst-wall, by examination by either the abdomen or the vagina, we must consider it a duty to see what tapping will do for a patient before adopting more serious measures. I think I have seen quite enough now to warrant me to endeavour to impress upon surgeons that, if the cyst be a single cyst, before they do anything else they should see what can be gained by one tapping. If the tapping be done with precaution, the risk is extremely small; the patient loses nothing, and may be cured. There are a great many cases recorded in my book to prove that fact, and also to show that the mortality of ovariectomy, supposing it afterwards becomes necessary, is very little affected indeed by previous tapplings. I gave a table showing what the effect of one, two, and many more tapplings, up to eighteen, had been upon the mortality, and the difference seemed to be very trifling.

In tapping through the vagina or rectum, a somewhat different instrument is used; either such a long instrument as that, or a similar trocar fixed upon an elastic catheter, which may be tied in and left, if necessary; or, if it be desirable to introduce a drainage-tube, then the instrument is much more curved. The point is carefully guarded by the finger, and, when one is quite sure where the point is, it is pushed into the cyst, and it is occasionally quite possible to introduce it near the uterus and bring it out nearer the rectum; to then attach a piece of drainage-tube to the slit in the point of the trocar, and draw it through, leaving it in the cyst after removing the cannula. That is not very easy to do; but I have done it, and in the days when more was thought of drainage than is the case now, it occasionally proved useful. It was used rather after ovariectomy, when a collection of fluid formed in the pelvis, than in treating ovarian cysts, because it would only be when the cyst was low down in the pelvis that it would be advisable. Sometimes, when there was a solid portion of the tumour high up in the abdomen and the more fluid portion in the pelvis, one could empty it in this way by the vagina or rectum. There was a discussion some years ago as to whether it was better to do it by the vagina or by the rectum, and at one time the argument was used that it was much safer to do it by the rectum, because there was a greater probability of air entering the cyst through the vagina; and the answer to this was manifestly that one would rather have an entrance of atmospheric air than of fecal gases.

Pressure following tapping was at one time very much the fashion; but I think it has entirely fallen into disuse. No surgeon now thinks very much of the use of long-continued pressure after tapping; it is very likely to inconvenience the patient, and may more probably occasion adhesions than if the patient be simply left alone with an ordinary amount of support. The formation of an intraperitoneal opening in a cyst-wall, I think, also is entirely abandoned. It was a proposition

made by Sir James Simpson of Edinburgh to cut a small piece out of the cyst-wall and then to let the cyst retract and empty. It is only in the single cyst that this could be of use, and in a single cyst the object would be much more simply and equally well effected by simple tapping.

With regard to the formation of a permanent opening through the abdominal wall or through the vagina, so as to cure a cyst by drainage, that may occasionally be useful, but I think only in very exceptional cases. It is a very tedious process; the patient remains for weeks, possibly months, in a state of great discomfort; she is exposed to the danger of suppurative action going on in the cyst, and to the fever which accompanies it, and it is only in exceptional cases that a cure is the result. I have seen patients cured in this way, but the cases have been few and far between.

Then, with regard to incision and drainage, making an incision into a cyst, and draining it when it cannot be removed, is not an intentional practice, but one to which a surgeon is driven who begins to do an ovariectomy and finds that he cannot complete it. The cyst is incised and emptied, and then it is found impossible to remove it. In that case, any portion of the cyst which has been separated may be fixed to the abdominal wall and the wound closed as far as is necessary, still leaving a sufficient opening for a tube to be passed low down to the bottom of the cyst, which may serve for drainage and for antiseptic injections. There are instances on record, apparently very hopeless, which have got well in this way. I have now a young woman acting as assistant to a nurse of mine, to whom last year this very thing occurred. The cyst was opened and was adherent everywhere; it was quite useless to attempt to separate it, so I closed the opening around a drainage-tube, and, after some months of drainage and syringing with carbolic acid, iodine, and other antiseptics, and at last with sulphurous acid, which seemed to act better than anything else in that case, it completely healed, and she is now in perfect health, and has made a recovery from what otherwise would have been a very hopeless condition indeed.

We will suppose now that we have a case to deal with in which tapping could be of very little use; or we will suppose that tapping has been tried; that fluid has re-formed after repeated tapplings; that all ordinary treatment has proved of no avail, then arises the question, "Is this a case in which ovariectomy should be recommended to a patient?" and the sort of common-sense rule that I have been in the habit of following has been to say to a patient, or to the medical man with whom I am in consultation: "So long as this patient is moderately comfortable, so long as she can walk a mile, or for half an hour, without much inconvenience, so long as she can get up and down stairs, so long as there is no great pressure upon any of the organs of the abdomen or pelvis, and she can breathe pretty well, and her heart is not interfered with, such a patient as that may be left to ordinary palliative treatment, with the usual attention to the general health." But I would also say that, if the operation be delayed for a time, she should not be subjected to any useless treatment; that it is quite useless to attempt, by iodine, or bromine, or lime, or by gold, or by any other remedy, to attempt to diminish the size of the tumour, or to check its growth. All that is quite useless, and might be very injurious to the patient. Then there comes a time when the patient is so far inconvenienced by the tumour, is so much distressed by its size, that she cannot move about without great discomfort; her general health is suffering; she is losing her rest, becoming thin, and some serious damage is being done by the pressure of the cyst; that is the time when the surgeon must interfere. The question then arises, With what prospect of success can the operation be done in any given case? Is this a case in which the patient will probably recover? or is it a case in which she will very likely die? Of course, that is the question which every patient presses upon the surgeon. She does not care to know that the mortality is 20 or 25 per cent.; she wants to know what the probability of her own recovery is, and that is the point one has to consider. Some patients will urge the operation upon the surgeon when they themselves are in very desperate circumstances. They may be almost at the point of death, and then wish the surgeon to step in and relieve them, they having previously resisted all advice from him. Quite lately, I saw a lady whom, a year ago, I strongly advised to have ovariectomy performed. She steadfastly resisted; she said she was old; she could get relief by tapping; she would get on as well as she could; and then, after some five or six tapplings, she gradually fell into such a state of suffering and exhaustion that, when the heart was almost stopping, she regretted that the operation had not been done earlier. It is necessary to explain to the patient that, if the operation have to be done, as it probably will have to be done, it must not be put off until there is no reasonable hope of its being performed successfully. In some cases, the surgeon, on the other hand, is pressed

to operate long before he thinks it is justifiable. A young woman wants to marry, or a wife wants to join her husband in India, or she does not like her appearance; unpleasant remarks are made about it, and then, in a case where the surgeon knows tapping will do but little good, the tumour being either multilocular or solid, he may occasionally, under such circumstances, operate quite legitimately and properly much earlier than he would if there were no such domestic reason.

With regard to the mode of estimating the risk of the operation in a given case, I should like to repeat the rule I laid down many years ago, that the probable result of ovariectomy can be estimated with far greater accuracy by a knowledge of the general condition of the patient than by the size and condition of the tumour; that from a patient with a good sound constitution one can remove a very large tumour having very extensive adhesions, and she will probably recover; whereas, among people who have been drunkards, or in whom the constitution has otherwise been impaired, or who have a feeble heart, unhealthy kidneys, or diseased liver, the operation is much more hazardous than in a healthy person. The size of an ovarian tumour alone has not appeared to me to affect the result very much; the removal of some very large tumours has been followed by recovery, whereas death has followed the removal of much smaller ones. And a patient who is accustomed to the life of a sick-room bears an operation much better than a person taken from the ordinary pursuits of active life and at once subjected to an operation. In consenting to operate upon patients who wished to go to the opera one night and to be operated upon the next day, I have learned by one or two rather painful lessons that it is far better to put off the operation till the patient is somewhat weakened or accustomed to the life of an invalid.

The size of an ovarian tumour alone, I say, does not very much affect the result; but, if it be a very large solid tumour, requiring a very large incision for its removal, the incision extending very nearly to the sternum, then the risk is very much greater. I have found, if a tumour could be removed by an incision not exceeding five or six inches in length, the mortality is considerably less than when it necessarily extends to nine, ten, or eleven inches. Adhesions, as I mentioned the other day, if only to the abdominal wall, do not much affect the result; if they be low down in the pelvis, the mortality is considerably increased by them.

Almost the only positive contra-indication to an operation, I think, would be the fact that the patient has some other disease which, if pursued its natural course, would certainly kill her. I do not think it would be right to perform ovariectomy on a patient dying with phthisis, although I have had to do it in the Samaritan Hospital with a patient in a very advanced state of phthisis; but she was suffering so much from the presence of the ovarian tumour, and was so urgent for relief, that I removed it, knowing very well the condition of her lungs. She lived for a month, very much relieved by the removal of the tumour, and I do not think her life was shortened by the operation; still her death a month after operation does somewhat affect the statistics. I think it is very rarely that one would be justified in doing an operation of that kind supposing one knows a patient has serious kidney- or liver-disease, or disease of any kind which, independently of the ovarian tumour, would, sooner or later, certainly kill her.

With regard to the suspicion of cancer, and how far that should decide the surgeon not to remove an ovarian tumour, I think, if one were certain it was cancerous, one ought to be content with tapping, removing any peritoneal fluid that might be formed around it, and not attempting to remove it. The disease would almost certainly return. But still again I have seen some very extraordinary cases in which I have removed ovarian tumours which appeared at first sight to be ordinary multilocular tumours, and where a careful examination showed evident proofs of malignant growth, yet the patients for a long time remained in good health. In one case, it was ten or eleven years before there was any return. So I think even the knowledge that a tumour was in all probability cancerous would not allow one to put operation aside altogether; but it necessarily obliges the surgeon to be very much on his guard.

I was going on to some other points as to the influence of age, social condition, and so on, of a patient upon the probable results; but the time is so short that I will now suppose we are about to do ovariectomy; and I will refer for a minute to the conditions under which it ought to be done and the preparation of the patient, the place in which she should be operated on, and so on. The place, I need hardly say, should be as healthy a place as we can find. The patient should be lodged in the best house, in the best sanitary condition, and in the best room, that can be secured for her. Then I do not know that I need say anything about her medical treatment before the operation, except simply that her bowels should be relieved, and any evident concentration of urine corrected by citrate of potash or some

other simple saline. Then, having procured a room for her either in a hospital or a private house, or in one of the nursing institutions which are now becoming common in London, the room must be so arranged that, after the operation, she can be kept perfectly quiet. The room must be well ventilated, though she must be protected from any current of cold air, and at the same time not overheated.

The table on which the operation is performed (it is useless to try to perform it on the bed) should be arranged near a window, so that the light falls on the table diagonally; then the surgeon does not stand in his own light, and the assistants do not interfere with him. The patient is brought in and lies down on the table. Her feet and legs are carefully wrapped up; and she is covered by a blanket, and a strap is fastened over her knees, so that she cannot throw her limbs about. It is well also to tie the hands; and nothing is better for this purpose than an ordinary bandage, making a loop, passing it over the sleeve of the dressing-gown, and tying the hands down to the legs of the table. Each hand should be tied down, and then she cannot interfere with the surgeon; and one or two assistants are thus dispensed with. In the next place, one wants to protect the clothing. If she have simply a night-dress on, with a flannel about her shoulders, she and the bedding are completely protected by the use of a sheet of waterproof cloth with a hole in the centre, around which on the inside adhesive plaster is spread to the extent of an inch or an inch and a half. That is thrown over the patient, and adheres to the skin of the abdomen, which, I should say, ought to have been previously well cleaned. The upper part of the sheet comes up nearly to the chin of the patient. Lately I have had it made larger; and we have a simple contrivance by which the sheet can be held up in order to protect the patient's face from the carbolic spray, supposing it to be used. The patient lying thus, with the gentleman giving chloroform at her head, she is completely protected by the India-rubber cloth from the spray, which is directed from the spray-producer and plays upon the abdomen.

We now suppose the patient is lying upon the table, and fastened there; the next thing to be done is of course to put her under the influence of some anæsthetic. I have no doubt whatever myself, from long trial of it, that the bichloride of methylene, as it is called, is a far safer anæsthetic than chloroform. Since I have used it, I believe in more than six hundred cases of ovariectomy and more than three hundred operations of other kinds, I have never once been in the smallest anxiety about a patient. Now, every surgeon here must know how very frequently, when chloroform is given, he is looking at the patient to see whether he is, I will not say likely to die, but whether he is not injuriously affected by the depressing influence of the chloroform. I can say for myself that several times, when chloroform was given in my earlier cases, I was extremely anxious about them. In two cases, I had to stop the operation and commence artificial respiration. I have seen several other cases in which, either at the time of the operation, or from protracted chloroform vomiting afterwards, the patient, if not killed, certainly had her chances of recovery considerably diminished, simply by the action of chloroform at the time of the operation or some short time afterwards. I have never seen anything of the kind which I think could be fairly attributed to the action of bichloride of methylene. Provided it is carefully given in a proper apparatus, I have never seen the smallest cause for anxiety. This apparatus was contrived by Dr. Junker a good many years ago. The bottle is graduated to contain an ounce of methylene. The administrator fastens the bottle to his coat, and the mask is placed over the mouth of the patient. Then, by simply acting on the bellows, the air passes through the methylene, becomes charged with the methylene vapour, and the patient inspires it in the quantity of methylene vapour which the air will take up. I am told by chemists this cannot exceed 4 per cent., but, as a rule, at ordinary temperatures, it takes up scarcely more than 2 per cent.; at any rate, you cannot get it to take up more than 4 per cent.; and diluted vapour, 4 per cent. of methylene and 96 per cent. of air, is positively safe. I have heard of two deaths from methylene, but it was not given with this apparatus; it was given in a sugar-loaf cone made of leather, with a piece of sponge or lint put into the cone and saturated with the methylene. This was placed over the mouth of the patient, who breathed the vapour of methylene without any mixture of air. That is rather death from suffocation, or death from too strong vapour of methylene, than death from methylene properly administered. I believe there has been one other death from methylene, in which it was administered by this very apparatus, but the circumstances were peculiar. I am informed the patient had been drinking the night before. Full particulars of this case have been sent to the Committee at Glasgow investigating this subject, for report at the next meeting of the British Medical Association at Bath. The bichloride of methylene, of which this is a specimen, I am told by Dr. Oscar Liebreich, is not really bichloride of methylene. Chemists have found that, if they obtained true bichloride of methy-

lene, they could not keep it—it very soon changes; therefore, it has a certain amount of impurity, a certain admixture of alcohol with it, by which alone it can be kept. If true pure bichloride of methylene could be made, it would cost about a guinea an ounce, and would not keep half an hour, so that this is a mixture of pure bichloride and spirit. I have seen it made. The chloroform and alcohol are placed in a retort with sheets of zinc and boiled; as distillation goes on, one atom of chlorine leaves the chloroform, and the zinc is converted into a chloride. Some people say it is only a mixture of chloroform and spirit; but that certainly is not true, because the vapour of it burns, while, as you very well know, the vapour of chloroform does not.

The nurses have sponges and water all ready—sponges of a certain size, thoroughly well cleansed and in sufficient number, neither too large nor too small. If they be too small they may be lost, and if they be too large they cannot be introduced. The assistants are ready. There are only two required: one stands opposite the operator to be prepared to assist him in tying any vessel, and more particularly in preventing the coming out of intestines after the escape of the cyst from the abdominal cavity. If the assistant be not careful as the cyst is drawn out, the intestines follow, and give a good deal of trouble; but, if he carefully hold up the abdominal wall, keeping the edges of the wound together, it is impossible that any intestine can follow the cyst as it escapes. He passes the middle finger inwards under the umbilicus, and the forefinger to the right and the thumb to the left of the wound, and holding the edges closely together as the tumour comes out of the abdomen. When I first saw ovariectomy done, and when I first did it myself, we were told always to have wet flannels and warm water to wrap up the intestines if they came out. I have seen all the intestines of a patient on the table wrapped up in warm wet flannels; the result was a quantity of wool from the flannels adhering to the intestines, which had to be cleaned off before they were returned.

Then, as to the instruments one uses. First, an ordinary scalpel—working rather with the point of the instrument than with the shoulder. Next we have a number of what are called my torsion-forceps, to hold any vessel in the abdominal wall. Supposing a vessel is bleeding, it is caught in a moment, and the forceps hang down holding the vessel, so that, when the peritoneal cavity is opened, no blood drops into it. I have them plated with nickel, so that they never rust. The bleeding vessels having been stopped, the next step is to divide the peritoneum, catching hold of it previously with forceps or by one of these little hooks. The advantage of the hook is that one is less likely to catch a bit of cyst with it. If the cyst be lying close to the abdominal wall when you are catching up the peritoneum with the intention of dividing it, you may catch the cyst also, and sometimes divide it as well as the peritoneum. That is avoided by using this hook. One or two flat touches of the scalpel on the peritoneum are sufficient to divide it. Then a broad director is passed into the opening, and, with a blunt-pointed knife, the peritoneum is very safely divided. I rather insist upon this blunt point, because, with a sharp-pointed instrument, supposing there is a bit of intestine adhering to the abdominal wall, it may be injured, or a sharp-pointed knife might enter the bladder if it were high up. Having laid bare the cyst by the incision of the peritoneum to the extent of three or four or five inches, it then becomes necessary to empty the cyst, and this is done by the form of trocar I have here, which is just one of the trocars I showed you for tapping, but of a larger size, and furnished with outer spring-hooks to fasten the cyst. It is passed into the cyst, then the point is withdrawn, and the fluid rushes through the cannula into the pail below the table. As that is done, the outer hooks are opened, the cyst is caught hold of and easily fastened to the cannula, and pulled out through the opening in the abdominal wall; the fluid passes out, the cyst is held by these grasping claws, and, if the cyst be free, it of course readily and easily follows the instrument. If any adhesion be noticed as the cyst comes out, it may be separated; but I must reserve any further description of that till the next lecture.

**BASFORD RURAL DISTRICT.**—Mr. Whitgreave commences his report by congratulating his sanitary authority because they will soon have what they have patiently waited for years—viz., a plentiful supply of pure water. The birth-rate is calculated to have been 42.64, and the death-rate 19.58, or 19.36 if 518 colliers who came into the district in 1877 be included in the population. There were 1,986 births and 912 deaths, so that the births were more than double the deaths. Inflammatory diseases of the lungs caused a large mortality, especially in the Greaseley registration district, which Mr. Whitgreave cannot account for. The mortality amongst infants was high, as 35 per cent. of the total deaths occurred amongst children under one year old; and 16.4 deaths under one year were registered to each 100 births, which is much above the average of rural districts in 1877. There is a full account given as to the removal of nuisances by the inspector.

## CONTRACTION OF THE FINGERS (DUPUYTREN'S CONTRACTION),

AND ITS SUCCESSFUL TREATMENT BY SUBCUTANEOUS DIVISIONS OF THE PALMAR FASCIA, AND IMMEDIATE EXTENSION.\*

By WILLIAM ADAMS, F.R.C.S.,

Surgeon to the Great Northern Hospital; Consulting-Surgeon to the National Orthopaedic Hospital; etc.

CONTRACTION of the fingers takes place from a variety of causes; and the pathological conditions will be found to vary according to the nature of the producing cause, such, for example, as local injuries, with laceration of tendons, deep abscesses in the palm of the hand, burn-cicatrices, etc. But in the present paper I propose to direct attention to one form only of finger-contraction, commonly met with in men about the middle or beyond the middle period of life—very rarely at younger ages. I have never seen it in women.

The contraction may affect one finger alone; in which case, according to my observation, the ring-finger is most frequently drawn down towards the palm of the hand, but some authors state that the contraction most frequently commences in the little finger. The contraction having commenced in one finger, however, the adjacent fingers are in most cases gradually drawn down, though to a less extent. I have frequently seen the ring-finger severely contracted, so that its tip would nearly touch the palm of the hand, and the middle and little fingers contracted to about half this extent. I have seen the contraction sometimes limited to the little finger. The index-finger and the thumb usually escape. I have never seen them more than slightly contracted. In these contracted fingers, the articulations are generally in a healthy condition; the joints can be flexed freely, but any attempt at extension is painful, from the resistance offered in severe cases by a tense contracted cord passing from the finger into the palm of the hand, to which the skin of the palm is closely adherent. The skin in the palm of the hand near to the base of the contracted fingers is commonly drawn into thick knotty folds.

The pathology and treatment of this form of finger-contraction always has been and still is the subject of much difference of opinion; and Dupuytren appears to have been the first surgeon to investigate the anatomical conditions by dissection. In the report of his clinical lectures,† it is stated that when Dupuytren heard of the death of a man who was the subject of this affection, he “was determined that this remarkable disease should not remain unknown. The arm was given to him, and he made a careful dissection. The skin having been removed from the whole extent of the palm of the hand and the palmar face of the fingers, the fold or the puckering of this structure entirely disappeared; it was, therefore, very evident that the arrangement which presented during the disease did not depend on this cause, but was communicated to it; but how, and by what? The dissection being continued, the Professor discovered the palmar aponeurosis extended, retracted, and diminished in length, its inferior part being divided into cords, which passed on to the sides of the affected finger. In extending the finger, he observed that the aponeurosis underwent a kind of tension or crispation—this was a ray of light; so he considered the aponeurosis was something in the effects [to be the cause, W. A.] of the disease. He cut the prolongations on the sides of the fingers, and immediately the contraction ceased, the fingers returned to a state of semiflexion, and by slight force to complete extension. The tendons were natural; the sheaths were not open; the articulations, ligaments, synovial membranes, and bones, were in their normal or natural state.” Since Dupuytren made this important contribution to our knowledge of this affection, it has been sometimes spoken of “Dupuytren's finger-contraction”: a title as useful as it is also a just compliment to the great surgeon, distinguishing it from all other forms of finger-contraction.

M. G. Goyrand‡ of Aix also records the dissection of the hand of a man, seventy-two years of age, affected with this form of finger-contraction; and the description agrees very closely with that of Dupuytren, although he regards the lateral bands extending along the phalanges not as digital prolongations of the palmar fascia, but abnormal fibrous fasciculi, which extend from the fascia to the sheaths of the flexor tendons, into which they are inserted opposite the second phalanx.

‡ *Gazette Médicale de Paris*, 1835, p. 481.

In the Museum of King's College is a dissected specimen of one of these finger-contractions, No. 1444-3 (see fig. 1), presented by the late Professor Partridge. In this specimen, the contraction is limited to the little finger, and shown to depend upon a strong contracted band of the palmar fascia *a*, by which the finger is drawn towards the palm of the hand, the fascial band stretching across like the string of a bow, and passing along the outer side of the little finger along the first phalanx to the beginning of the second. The flexor tendons *b* are seen lying deeply along the concavity of the curves close to the bones.

This dissection has also been figured in Druitt's *Surgeon's Vade-Mecum*, eleventh edition, fig. 301, and I am indebted to Dr. Druitt for permission to reproduce it here (see fig. 2). In this drawing, the direc-

tion and relations of the contracted band of the palmar fascia are more distinctly shown, but the relation of the fascia to the tendons had not been demonstrated by dissection at the time when this drawing was made.

There is a cast in the Museum of King's College apparently taken from the same subject previously to the dissection, as it corresponds in all respects with the contraction of the little finger, and shows the lateral direction of the contracted fascial band. (Fig. 3.) This cast has no number, but is engraved June 1853, and I am informed that Mr. Partridge always used it in lecture, together with the dissection.

It has never occurred to me to have the opportunity of dissecting one of these finger-contractions; but on April 15th, 1864, a gentleman, Mr. L., aged 50, residing at Hampton Court, who suffered from Dupuytren's contraction of the fourth and fifth fingers in each hand, and upon whom I had proposed to operate, met with an accident. In attempting to hold a restive horse, the contracted fingers on the right hand were suddenly torn open and the skin in the palm of the hand torn across. I saw him shortly after the accident, when the hand had been merely tied up by a handkerchief, and found a large gaping wound in the palm of the hand, reaching nearly half way across. The palmar fascia had been torn across, together with the skin, but the sheaths of the tendons were not torn, and it was evident that these structures had not been implicated in the contraction. The tendons in their sheaths were seen lying at a depth from the surface, running along the concavity of the curve in proximity with the bones, whilst the fascia had evidently been stretched across, like the string of a bow. After cutting away a few torn shreds of fascia, I found, on attempting to extend the fingers, that the previously transverse wound assumed a lozenge shape, in a perpendicular direction. I therefore approximated the edges laterally, and introduced sutures, so that when

sewn up it resembled a longitudinal instead of a transverse wound. The hand was firmly bound round with narrow strips of plaster, and bandaged to a splint, with the fingers in an extended position. On the third day, the wound presented a healthy appearance, without any suppuration, and I therefore removed the sutures; the healing process proceeded without interruption, and the fingers remained nearly straight, without their power of flexion being lost.

These, so far as I know, are the only facts to which we can appeal for the anatomical conditions presented in Dupuytren's finger-contraction; and they all agree in negating the supposition that the tendons or sheaths of the tendons are involved in these contractions. This is also confirmed by my own clinical experience, as I have invariably found that, after dividing subcutaneously a tense and prominent cord, which has generally been mistaken for a tendon, in the palm of the hand, the patient is immediately able to flex the finger as strongly as before the operation, at once disproving the opinion often expressed by surgeons that such fingers will remain stiff and inflexible after the operation.

The commencement of this form of contraction is sometimes to be traced in one hand, in patients in whom the contraction exists in a severe form in the other, and I have watched its commencement from a flattened nodular induration in the palmar fascia in or just above the transverse crease in the palm of the hand corresponding to the metacarpophalangeal articulations. In the beginning, the skin is not adherent to this flattened induration; but in one case now under my observation, the commencement of a fascial-cord contraction can be traced, leading from the transverse crease to the little finger in the left hand: a spot certainly not exposed to pressure.

In the *second stage*, the skin becomes adherent to the thickened fascia, and a puckered dimple is produced, extending from which towards the finger a thickened band of fascia can be distinctly felt.

The *third stage* consists of an increased thickening of the palmar fascia and the band leading to the finger; and also the formation of a thick cord-like band of fascia, leading from the central thickening towards the annular ligament of the wrist, accompanied with a gradually increasing drawing down of the finger or fingers towards the palm of the hand. Such I believe to be the gradual progress of the fascial contraction and its adhesion to the skin in Dupuytren's finger-contraction.

*Cause.*—With regard to the cause of this affection, most authorities agree in assigning it, in the great majority of cases, to a local cause, and believe it to be produced by pressure from the use of tools in various occupations; and it is said that carpenters, gardeners, and gunners, are specially liable to it. Sir James Paget refers to the elder men occupied in wire-drawing and lock and key-making, as being subject to this condition. It is also generally admitted that this form of contraction may take place from constitutional causes, independently of any local cause, and that it is then traceable to a gouty diathesis. Sir James Paget\* points out the dependence of this contraction in some cases upon the gouty diathesis, and believes that the adhesion of the palmar fascia to the adjacent sheaths of tendons and the integuments forms a point of diagnosis. My own opinion is that it nearly always depends upon a constitutional rather than on any local cause, and essentially I regard it as depending upon a gouty diathesis. In favour of this opinion, I would refer, first, to the class of patients in whom it occurs. During a connection of more than twenty years with the Royal

Fig. 3.—Cast from the Hand represented in Fig. 1, previous to dissection.

\* Abstract of Clinical Lectures delivered at St. Bartholomew's Hospital (BRITISH MEDICAL JOURNAL, May 22nd, 1875, p. 665).

Orthopaedic Hospital, I have seen but very few cases of Dupuytren's contraction in the labouring class; and the cases that did present themselves generally occurred in butlers and in-door servants. It seems, however, to be an affection of common occurrence in the middle and upper classes of society. The cases which have fallen under my observation have occurred in clergymen, barristers, medical men, officers of the army and navy, and merchants; the only condition common to the whole series being a disposition to gout. Coexisting with the finger-contraction, in the cases which I have seen there have been generally other manifestations of a gouty tendency, more especially to that form we recognise as rheumatic gout affecting several articulations and often causing enlargement of the joints of the fingers rather than true inflammatory gout, affecting the great toe. Secondly, I would refer to the frequent occurrence of this affection in the left hand only, and to its occurrence in both hands, which we can hardly explain by any local cause. Thirdly, I would refer to the fact that in several instances I have known two brothers suffer from it; and in some cases, the father and son have been similarly affected; so that, for these reasons, I am disposed to attach far greater importance to the constitutional than to any local cause.

*Treatment.*—With regard to treatment, this must be either mechanical or operative; and there can be no doubt that gradual mechanical extension, by an apparatus worn night and day, or in slight cases only at night, would not only prevent increase of the contraction, but diminish, and possibly even cure it when slight and not of long duration. But in severe cases, and in those of long standing, mechanical treatment is useless, the only prospect either of benefit or cure being from operative treatment either by open wound or the subcutaneous method.

Dupuytren, in the year 1831, divided the contracted palmar fascia by open wound, making an incision ten lines in length; but a second and even a third incision was found to be necessary. Dry charpie was applied, and the fingers extended. Inflammation and suppuration followed; and at the end of nearly two months, it is reported that "the fingers regained their natural condition".\* Two other successful cases are also reported in the same lecture.

Mr. South,† in his translation of Chelius, states that "Goyrand does not divide the skin transversely, as Dupuytren does, because in straightening the finger, the cut in the skin gapes too much; but he cuts through it longitudinally and through the bridge transversely".

Dr. Otto W. Madelung‡ has recently published an account of the treatment of these cases adopted in the Surgical Hospital at Bonn by Professor Busch. This operation belongs to the class of open wounds, and consists in dissecting up a triangular flap of skin from the contracted cord in the palm of the hand, and then dividing all the bands of the contracted fascia which can be reached; as the flap thus raised contracts, the lower points of the wound may be united by sutures. "A light bandage closes the wound; the hand is then kept by the patient in a sling, without the slightest attempt to preserve the extension. . . . Extension-movements with the fingers are only made when the wound has entirely granulated, and then only in a light gentle way. At first, wood cylinders of various sizes are laid in the hand; later, the hand is stretched on a back splint. Active and passive movements are now to be made in, and during the time the hand-bath is used for cleansing the wound. More complicated apparatus than the above are never required. The healing of the wound, accelerated perhaps by skin-grafting, is accomplished in three or four weeks."§ Successful cases under treatment are referred to, but one is added by the author in which, notwithstanding the use of Lister's antiseptic treatment, suppuration with sloughing of the flexor tendon of the little finger took place; but this is stated to be the only unfavourable case.

Professor Alfred C. Post of New York also operates upon these cases by open wound, making incisions at a number of points, but not longer than absolutely required, as he believes that the adhesion to the skin prevents a strictly subcutaneous section from being made. He advocates immediate extension on a metal splint; the dressings to be removed every two or three days, and passive motion applied. Of the four successful cases cited by Professor Post, only one seems to have been of Dupuytren's contraction, the others depending on abscesses and traumatic inflammation.

All operations by open wound for these cases should be condemned as unnecessarily severe, involving a long and tedious reparative process, with the risk of suppurative inflammation, and also a liability to failure, in which event the condition of the patient would be worse than before the operation; contraction from cicatrix being one of the most difficult conditions to relieve. Nevertheless, in England, the operation by open wound has long been practised by the majority of surgeons, and is still recommended in some of the text books, when the subcutaneous operation has failed, as it is generally supposed to do. There is, however, in England, a very general distrust in all operative procedures in the treatment of this affection, which is regarded as incurable, the patients being advised to bear the ills they have, rather than run any risk from suppurative inflammation, with the doubtful gain of a stiff and useless finger.

The operation which I now propose to bring before the notice of the profession is not based upon any new principle in surgery, as the subcutaneous division of the palmar fascia for contracted fingers has been practised, both in this country and on the Continent, for many years. Within the last few years, I have materially modified the details, both with regard to the mode of performing the operation and the after-treatment. The success has been found much greater, and the treatment much less irksome to the patient, as well as of shorter duration, than the method of operating and the after-treatment which I adopted in the earlier part of my practice from the teaching of my late colleagues and predecessors at the Orthopaedic Hospital, Mr. Tamplin and Mr. Lonsdale. They believed that both fascia and tendon were involved in the contraction, and divided the contracted cords in the palm of the hand in the same way as they divided tendons: subcutaneously, cutting from below upwards and making only one puncture. They also adopted the same method of after-treatment, by gradual mechanical extension; using complicated steel instruments, with cog-wheels opposite the joints of the fingers. Further study of these cases, and the opportunity which was accidentally afforded me of seeing that the tendons were not involved in a severe case of finger-contraction previously referred to, in which the palm of the hand was torn across by a horse, confirmed me in the belief that the tendons were not implicated in this form of contraction of the fingers, and that surgically we had to deal with contraction of the palmar fascia alone, as Dupuytren had described the affection. I therefore commenced the practice of making multiple subcutaneous divisions of the fascia, introducing the smallest tenotomy knife—smaller than any ordinarily used, as shown in fig. 4—and carrying it between the skin and the contracted cord, which I then divide by cutting downwards very slowly and cautiously, taking care not to dip the point or divide any structures, except the contracted band of fascia. In one case, where three fingers were contracted, I made as many as nine punctures and subcutaneous divisions; but where so much is required to be done, I think it generally advisable to confine the operation to one or two fingers, making not more than five or six punctures—in many cases, four will be found sufficient—and leave the other finger or fingers to be treated at a subsequent operation. As a rule, I make the *first puncture* at the greatest distance from the finger, in the palm of the hand, towards the annular ligament, a little removed from the point where the skin is adherent to the fascia, and where the skin is not tightly stretched over the contracted cord, so that the tenotomy-knife can be readily introduced between the two. The *second puncture* should divide the same cord as the first, but as near to the finger as possible, thus leaving the contracted band in the palm of the hand, when adherent to the skin, isolated and cut off from its connections at its upper and lower extremities. The *third and fourth punctures* divide the lateral bands or digital prolongations of the palmar fascia, which usually pass from the central cord in the palm to the adjacent sides of the fingers. These must be divided very carefully in order to avoid cutting the vessels and nerves along the sides of the fingers; the punctures should be made at the bifurcation of the cutaneous net between the fingers, and the incisions directed obliquely upwards and outwards towards the palm of the hand. These incisions will divide the strongest and most prominent bands, which produce the flexion of the first phalanx of the finger upon the hand, and if care be taken to avoid dipping the point of the knife, there will be no fear of wounding vessels or nerves. Sometimes lateral bands of contracted fascia require to be divided opposite the centre of the first phalanx, and this must be done by puncture at the edge of the contracted bands, the knife being directed transversely towards the bone; but this cut must be made very carefully, to avoid the artery and nerve; the surgeon remembering that the band, though tough and strong, is at the same time very thin. These bands are more readily cut through with the scissor-pointed tenotome, *i.e.*, with the point at the extremity of the straight cutting edge, represented in fig. 4. The central-pointed tenotome generally used does not divide

¶ On Contraction of the Palmar Fascia, and of the Sheaths of the Flexor Tendons, by Alfred C. Post, M.D., of New York (*Archives of Clinical Surgery*, August 1877).

the fascial bands so readily or with the same precision. Occasionally a lateral band may have to be divided between the first and second phalanges, at a point corresponding to the articulation, and this must be done very carefully and with the precautions just described. I

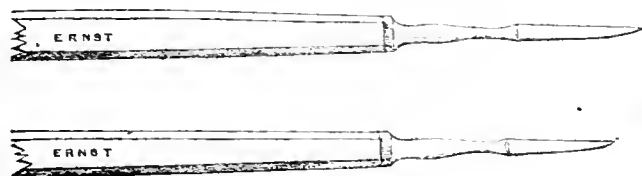

Fig. 4.—Small Knives used for division of the Bands of Fascia.

always avoid making any central incisions in front of either the first or second phalanx, as the sheath of the tendons, or the tendons themselves, may be readily divided by such incisions, and would lead to a loss of the power of flexing the finger after the operation.

Subsequently, I also adopted another important modification in the after-treatment of these cases; viz., the plan of immediate extension, bringing the finger or fingers as nearly as possible into the fully extended position at the time of the operation, and afterwards applying

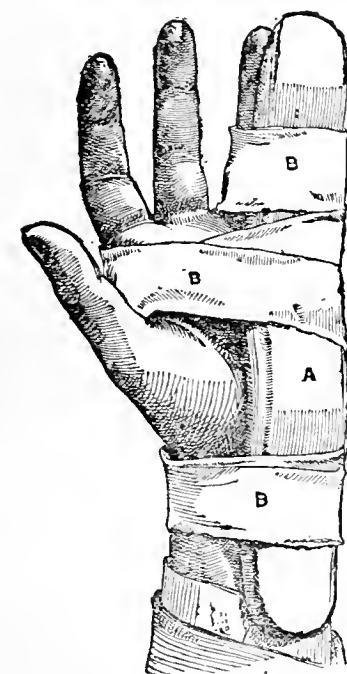

Fig. 5.—Retentive Metal Splint to which the Fingers and Hand are bandaged after the operation.

and after-treatment, I have had good reason to be satisfied with the results, and in the great majority of the cases operated upon, the contraction has been completely and permanently removed.

**Anæsthetics.**—With regard to the employment of anæsthetics in these operations, which must necessarily be done slowly and very carefully, several punctures being made, I have always advised the use of chloroform or ether. I abandoned the use of ether-spray, after employing it some years ago, because it was found to harden the skin, so as to make the puncture difficult and obscure the anatomical relations of the parts. It occurred to me, however, that if I rapidly thawed the frozen skin by rubbing it with my own hand, the deep anæsthesia would probably remain long enough for a subcutaneous operation; and this I have found to occur. In the case of a medical friend, Mr. R., upon whom I operated for contracted fingers in January 1877, and who objected to take either chloroform or ether from the condition of his circulation, I made four punctures, and he only felt one of them, and that very slightly. The objection of hardening the skin, therefore, being done away with, the local anæsthesia by the ether spray is now found to be applicable to tenotomy and some other subcutaneous operations, as its inventor, Dr. Richardson, originally thought it would

be. The hand of the gentleman alluded to, Mr. R., is represented in fig. 6, showing severe contraction of the middle and ring fingers of the right hand previous to operation; and its improved condition one

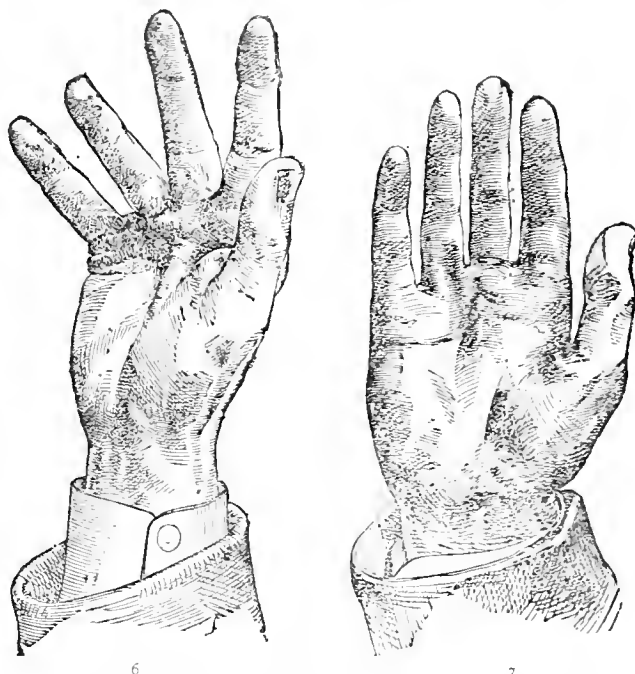

Fig. 6.—Hand showing Dupuytren's Contraction of Middle and Ring Fingers, with prominent Cord in Palm of Hand. From a cast.

Fig. 7.—The same Hand as shown in fig. 6, one year after operation. From a photograph.

year after the operation is shown in fig. 7. The fingers are perfectly straight and useful, the voluntary power not having been interfered with by division of tendons.

A severe degree of contraction of three fingers is represented in fig. 8; and the same hand is shown in fig. 9, thirteen years after the operation. The middle and ring-fingers remain completely cured, with full power of flexion, and all trace of contraction in the palm of the hand has disappeared. The little finger, which never could be brought quite straight from alterations in the joint said to be the result of injury, remains contracted between the first and second phalanges. This gentleman held and still continues to hold a consular position, and the contraction of three fingers in the right hand so much interfered with his ability to write that his signature was scarcely legible. His writing powers were completely restored by the operation.

**Summary.**—The operation and treatment which I now practise may be described as follows.

1. The subcutaneous division of all the contracted bands of fascia which can be felt; the bands to be divided by several punctures, with the smallest tenotomy-knife passed under the skin and cutting from above downwards; a pledget of lint being at once placed over each puncture and retained in position by a strip of plaster.

2. Immediate extension to the full extent required for the complete straightening of the fingers, where this is possible, and the application of a retentive well-padded metal splint from the wrist along the palm of the hand and the fingers; the fingers and hand to be bandaged to the splint.

3. The bandage not to be removed until the fourth day, when the lint and plaster may also be taken off, as the cutaneous punctures are always found to be healed by the fourth day. The retentive metal splint to be reapplied, and the hand and fingers bandaged to it.

4. Extension to be kept up by the splint worn continuously night and day for two or three weeks; but the splint and bandage to be changed every two or three days. After this, the extension splint is to be worn at night only, for an additional three or four weeks, free motion being encouraged during the day.

**Relapse of the deformity,** I believe, is now guarded against by the plan of dividing all the contracted bands of fascia by as many punctures as may be necessary; and, in severe cases, not attempting too much at one operation; and also by the adoption of the plan of immediate ex-

tension. If partial relapse should occur—and I have never known more than this—any hands that may have escaped division, or any which may since have become prominent by the extension, may be

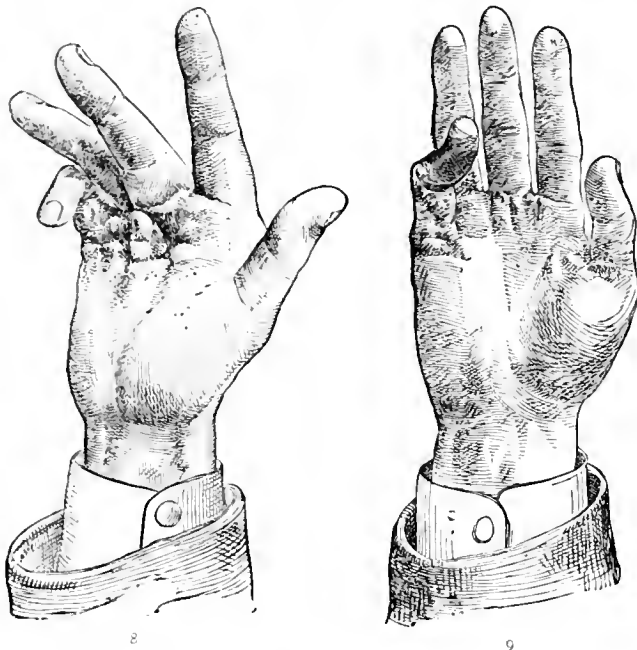

Fig. 8.—Hand showing Dupuytren's Contraction of Middle, Ring, and Little Fingers. From a cast.

Fig. 9.—The same Hand as shown in fig. 7, thirteen years after operation. The Middle and Ring Fingers remained completely cured, with full power of Flexion; and all trace of Contraction in the Palm of the Hand had disappeared. The Little Finger, which never could be brought quite straight, from alterations in the joint, said to be the result of injury, remains contracted between the first and second Phalanges. From a cast.

divided subcutaneously, and the disposition to recontraction prevented. This contrasts very favourably with the relapsed cases after open wound, which from the nature of the cicatricial contraction are incapable of further relief.

It has been my object in the present paper to give to the profession an increased confidence in the subcutaneous operation for Dupuytren's contraction of the fingers, and to point out a number of details in the mode of performing the operation and in the after-treatment, upon which I believe much of the success will be found to depend.

## THE TREATMENT OF ACNE.

By JAMES STARTIN, M.R.C.S.,

Surgeon to 1. John's Hospital for Diseases of the Skin.

AUTHORS and writers, from the earliest ages up to the present day, seem to have considered the successful treatment of acne, particularly that form known as *acne rosacea*, to be of some considerable difficulty. I have been much rewarded lately, in hospital and private practice, with some very good results by the carrying out of the following mode of treatment.

In the first place, vegetable acids, mineral waters, purgatives, arsenical preparations, and other specifics, are not indicated in this eruption of the skin, nor have I ever found them of much avail. The diet should be carefully regulated, all indigestible food avoided; and little or no stimulant should be allowed, except in those cases where the powers of digestion should require slight excitation to perform their proper function; and the discriminate use of chalybeates, combined with mineral acids, vegetable bitters, and tincture of iodine, I consider to be the most useful internal remedies. These are considerably augmented by the sulphur-vapour douche or vapour-bath.

But it is the external treatment that is most important, and it is to this that I wish to draw more particular attention. If, at the onset of the affection, the sebaceous glands and follicles become overloaded, they should be relieved by pressure between the finger and thumb-nail, and by frequent washings with warm water and oatmeal; after which a good rubbing with a flesh-brush will remove the contents of a

number of the pimples; and, if the disease be more advanced and the indurated spots become enlarged and painful, the vapour-douche is then of much service, followed by an ointment of the ammonio chloride of mercury and camphor, or the gentle application of iodide of sulphur ointment at bedtime, and the use of a cooling zinc or calamine loion, to be painted upon the face with a camel-hair brush two or three times a day. With the judicious use of the above remedies and applications, I may probably nearly remove and cure the disease; but troublesome redness, with often great vascularity, still remains in spite of treatment, and it is to this stage of the affection my remarks tend. To those small indurations and superficial venous enlargements and plexuses, I generally apply the acid nitrate of mercury with care by means of a spun-glass brush. One or two applications, with the immediate use of bibulous or blotting paper afterwards, will usually suffice to effect complete obliteration without a scar; and I find, after a few days, the morbid states of the capillaries have undergone a complete change for the better. Nevertheless, we may still have some of the larger capillaries, which keep up the localised redness and induration, to contend against; then the mercurial acid treatment does not hold good. I therefore divide each engorged vesicle with the point of the lancet; and, should the hæmorrhage be much, I apply a small ring of silver or steel, which I have fixed into a handle at right angles, and about the eighth of an inch in diameter, over the two divided ends of the vessel. I then insert a minute grain of nitrate of silver, which at once stops the bleeding and obliterates the engorged conspicuous vesicle, leaving only a small black discoloured spot, which may be easily removed by the application of a solution of iodide of potassium.

The above treatment may appear somewhat heroic for so common an eruption. I can only state that I have made use of it in a large number of cases, and find it to be the most successful mode of cure.

## GOITRE AND THE HÆMORRHAGIC TENDENCY.

By R. BRUCE LOW, M.D.,

Medical Officer of Health, Helmsley Rural Sanitary District.

IN the course of my reading, I have been unable to find any mention of the fact that goitrous persons are peculiarly subject to hæmorrhages. As I reside in a district where goitre abounds, I have had opportunities of remarking the frequency of flooding among the women, and more especially among the women with goitres. During the last few months, I have collected notes of one hundred and eighty-three cases of goitre. Of these, there were ninety women who had borne children, and, out of these, thirty-one were habitual flooders; besides these, a considerable number of others showed a hæmorrhagic tendency, especially at their menstrual periods. There appears to be a great predisposition to flooding in the district, so much so, that the medical men of the neighbourhood are united in their opinion that more care and attention are requisite after labour is over here than in other districts. Even with the greatest care, flooding sets in. For example: in a case where a goitrous woman was confined safely and the placenta removed, I grasped the contracted uterus through the abdominal wall, and held it firm for more than an hour; but, feeling exhausted, I transferred my post to an attendant, with the effect of seeing the woman flood and faint exactly four minutes after I left hold of the uterus. In cases, again, where labour is over before the arrival of the medical man, flooding is very apt to go on to a very serious extent. The tendency to flood is not entirely confined to goitrous women in the district, but these are usually the worst cases.

The etiology of goitre is still far from being clear; but it is now accepted that the disease is endemic in certain well-defined geological districts, and also that it may be produced by some bad hygienic conditions, *e.g.*, dampness, overcrowding, and bad ventilation. The water-supply of the Helmsley district is pure and good, but, owing to its situation on the oolitic lime-stone formation, the water contains carbonate and sulphate of lime and, in smaller quantity, magnesia. The permanent hardness is not great, the water being used for washing and other domestic purposes. It contains no trace of iron. The district is extensively wooded, and is intersected by numerous small valleys, which are constantly filled with damp foggy emanations. The dwellings are small, badly constructed, ill-ventilated, and generally overcrowded. Many of them are in bad repair. The people, for the most part, are engaged in agricultural pursuits. Inter-marriage has hitherto prevailed to a great extent, the isolated position of the district having prevented the inhabitants from mixing with those of other neighbourhoods.

Many medical men have called attention to the evils which arise from the continued use of water impregnated with lime and magnesium salts. Dr. Murray, in an able paper in the *BRITISH MEDICAL JOURNAL* for

September 28th, 1872, mentions a number of diseases which arise from water so contaminated. Among others, he names goitre, cretification of the arteries and valves of the heart, rheumatic arthritis, and calcareous deposits in various organs. In this district, anaemia is soon produced, when young females, especially from the South of England, come to reside here. This is a most frequent occurrence among the domestic servants of the neighbourhood. The majority of the young girls, living in the small farm-houses scattered over the moors and in the sequestered valleys, are highly anæmic in appearance, and are often under treatment for that condition.

Pregnancy has a powerful effect on goitre. Many bronchoceles appear during the first pregnancy, or are noticed immediately after the first labour; the popular notion being that the swelling is due to the exertion of bearing down during the expulsion of the child in delivery. An eminent continental observer has shown that, in pregnancy, there is enlargement of the thyroid gland; there are fewer red blood-corpuscles, and there is a watery state of the blood; the tone of the system is reduced, as in those who show a goitre from bad hygienic conditions or surroundings. The thyroid is a vascular organ; and those causes which reduce the tone of the system reduce the tone of the vaso-motor nervous system and dilate the vessels: thus the circulation is rendered slower. This allows exudation of white cells to take place into its tissue, and produces degeneration of the thyroid gland. Many goitres disappear after the climacteric period.

The results of these observations may be summed up as follows.

1. The water-supply in limestone districts has a powerful influence in deteriorating the blood, causing dyspepsia, anaemia, and a want of contractile power in the blood-vessels, as shown by the development of goitre and tendency to hæmorrhages, more especially flooding in childhood.

2. Goitre and the hæmorrhagic tendency are aggravated, and sometimes even produced, by certain conditions: *e.g.*, overcrowding, bad ventilation, and damp dwellings.

3. Pregnancy assists in the development of goitre and the hæmorrhagic tendency.

4. The predisposition to goitre and "flooding" is affected by consanguinity and heredity.

5. The best treatment for both conditions is change of locality, and the prolonged administration of some preparation of iron.

## CASE OF RETENTION OF MENSTRUAL FLUID IN THE FALLOPIAN TUBE: A REPLY TO DR. HARLEY.

By LAWSON TAIT, F.R.C.S.

I AM quite satisfied to accept Dr. Harley's criticisms in the spirit in which they are offered; but I greatly regret that he did not more fully investigate the subject before he made them. For what he is pleased to call his "speling", I trust he has better arguments.

First of all, he asserts that no menstrual fluid (proper) is secreted by the Fallopian tubes. Dr. Harley jumps to this conclusion, because he found no menstrual fluid in the tubes of a woman who was not menstruating, but only on the point of doing so. I have, on the contrary, more than once seen menstrual fluid in the tubes of women who have died during menstruation, though I am by no means certain that this is a constant phenomenon, as I can recall two instances where it was looked for and not found. On page 1 of the Sydenham Society's translation of Bernutz and Goupil's *Diseases of Women*, the following sentence may be found; and, so far as I have seen, Dr. Harley stands alone in his opposition to the view it expresses concerning the share the Fallopian tubes have in menstruation: "Soon the cavity of the tubes is dilated by a bloody mucus, which mixes in the uterus with the blood exhaled by its cavity, now lined by an imperfect decidua, and then escapes by the open cervix."

Besides this, we sometimes see menstrual fluid poured from the divided end of a Fallopian tube after ovariectomy. A few months ago, I was obliged to operate on a woman during menstruation, and, for reasons irrelevant here, I did not include the tube in the clamp. For several days after the operation, menstrual blood flowed from the tube in considerable quantity. Dr. Harley's division of menstrual fluid into "proper" and (by inference) "improper", I do not profess to understand. I am quite content with the evidence I have met with, that the Fallopian tubes, in at least some instances, contribute towards what is usually recognised as the menstrual fluid.

That my patient is not the subject of bifid uterus I am quite certain; and for this I have the evidence of my two hands, between which

I had the organ, after I had performed abdominal section. Even if the uterus had been bifid, the case would have been quite within the category in which I placed it, as I am sure Dr. Harley's knowledge of comparative anatomy will enable him to see. The point made by my critic, to the effect that it could not have been the Fallopian tube, because the wall of the cyst contained an abundance of unstriated muscular fibre, must be really amusing to any one familiar with Dr. Arthur Farre's observations. We all know that muscular cavities, when distended by such a condition as I suppose to have taken place in this Fallopian tube, have their walls hypertrophied, and that, when emptied, their walls contract vigorously; and, therefore, it was not surprising that the cyst contracted after being emptied. That I could not find a canal leading into the uterus was probably due to the closure of the aperture, as I suggested in my paper. If it had been a double uterus, I should have expected the cavity to run down for some distance alongside the other undilated half. But it did not. The cyst had an intimate relation to the cornu of a perfectly normal uterus; and this it was which chiefly led me to recognise at once that I was dealing with a dilated Fallopian tube.

I said, at the conclusion of my short and perhaps inadequate account of the case, that the recovery of the patient left a good deal of speculation; but certainly, what is so left does not include any of the points raised by Dr. Harley, and this he may easily satisfy himself upon by consulting the literature of the subject. Thus I may direct his attention to a case published by no less an authority than Dr. Meadows, in the eighth volume of the *Obstetrical Society's Transactions*, in which the conditions seem to have closely resembled those in the case I published, with this difference only, that both tubes were affected instead of one; and that, by the death of the patient, an opportunity was afforded of ascertaining what the exact pathological conditions were. Here they are described: "It was found that both Fallopian tubes were enlarged, not regularly or uniformly, but so as to form a kind of cyst. On the right side, there were two such enlargements, on the other, one. There was no evidence of any communication between these dilatations and the fimbriated opening. On the left side, there was not even an opening into the uterus, the ostium uterinum being completely occluded. They were all filled with a dark, thick grumous fluid, of a prune-juice colour. It is evident that, in this case, we have an example of what MM. Bernutz and Goupil contend for, viz., menstrual retention within the Fallopian tube. The one fact which is clearly revealed is, that the Fallopian tubes do, as well as the uterus, take part in the menstrual secretion; and hence, when any obstruction occurs to the passage of that secretion into the uterine cavity, and so externally, we get the resulting symptoms of menstrual retention."

Other cases of an exactly, or nearly, similar kind are on record; but I am quite satisfied to rank with such observers as Bernutz, Goupil, and Meadows, even at the risk of Dr. Harley's criticism, by which I have in no way been induced to modify the title under which I published my case, or to alter in the least my views regarding it.

## THERAPEUTIC MEMORANDA.

### MILK AS A VEHICLE FOR QUININE.

It is not, I believe, generally known that milk is an elegant and convenient solvent for quinine, and that it disguises to a great extent its bitterness. If one grain of sulphate of quinine be dissolved in an ounce of milk, we shall find that the bitterness of the draught is hardly perceptible; with two grains there is rather more bitterness, but it is not at all marked. A dose of five grains may be taken in two ounces of milk without an unpleasantly bitter taste; and if the same quantity be put into a tumblerful of milk, the bitterness is all but lost. This method of administering quinine must in some cases be preferable to the ordinary way of dissolving it in acid or spirit, especially where the bitter taste is objected to (as in the case of children), or where the required dose is large; and it will, doubtless, be found to possess other advantages.

R. L. BATTERBURY, M.B.Lond., Berkhamsted.

### GLYCERINE IN INTERNAL HÆMORRHOIDS.

AFTER reading Dr. David Veung's paper in the January number of the *Practitioner*, which is referred to in the *BRITISH MEDICAL JOURNAL* of June 1st, I was anxious to make a trial of glycerine for this troublesome complaint. I have now used it three or four times, and each time its administration was followed by marked relief. Especially was the relief most observed in a young man aged twenty-one, suffering from advanced phthisis. This patient's life was rendered miserable for

some time by the intense pain caused by some internal hæmorrhoids, his sleep was disturbed, and, as he said, he was not free from pain night or day. I used several remedies, including confection of senna, without any success; so I determined to try glycerine, which I did, giving it in one drachm and a half doses every three hours. After taking this for twenty-four hours, the patient's pain was much relieved, and after forty-eight hours it was entirely gone. I may say, however, that the cure was not permanent after leaving off the medicine, as he has had several attacks of pain since, but never so severe as before. He keeps some of the glycerine mixture by him, and a few doses always have the desired effect.

I think that, in such cases as these, we may find glycerine a most valuable therapeutical agent, the oleaginous nature of which may, perhaps, make it useful in other ways in phthisis. In the case of which I speak, the state of the patient's lungs entirely precluded operative interference, so that a remedy of this kind was particularly serviceable.

W. H. JALLAND, F.R.C.S., York.

## REPORTS AND ANALYSES

AND

### DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

#### NEW TRACTORS FOR MIDWIFERY-FORCEPS.

WHEN I had once thoroughly examined the ingenious new midwifery forceps of M. Tarnier, I saw immediately that his principle gave to those who used the instrument a new power, or rather the ability to use power, in a new direction. I set to work to try if the best part of his principle could be arranged in an effective, portable, and cheap form, so as to be applied to the different patterns of existing long curved forceps. My objections to M. Tarnier's instrument are, that it is bulky, cumbersome, costly, and not very easy of application, though it is most valuable when once *in situ*. After several experiments and much unavoidable delay, I have succeeded in getting made a pair of tractors, which can be hooked on any long curved forceps (after application), can be as readily detached (Tarnier's are fixed by a hinge-joint), and are very portable and cheap.

By means of my tractors, one can use power in a new direction—viz., in the middle of the curve of the forceps, instead of in the long axis of the handles; or one hand may work the tractors and the other the handles in some cases with advantage. The tractors alone give power in such a direction as can only be got in the ordinary way with both hands, or by a leverage of the wrist. I am accustomed to slip an India-rubber ring (about twice as large and strong as those used for umbrellas) on the handles of the forceps when *in situ*: this is better than tying with tape, as it yields somewhat, and accommodates itself to circumstances. The handles, when thus fastened (as shown in the woodcut), move in the direction in which traction ought to be

made, and so form a safe guide in what direction to pull.

I have been well satisfied with the performance of these tractors, so I make them known at once to the medical world, though I quite believe that they are capable of improvement. They can be supplied by Messrs. Maw, Son, and Thompson, of 12, Aldersgate Street, at a very small cost.

HERBERT M. MORGAN, L.R.C.P., M.R.C.S.

#### A NEW MODIFICATION OF THE TELEPHONE FOR MEDICAL PURPOSES.

INTERESTED in common with most people in the microphone and telephone, I have felt some hopes that the deaf might be in some way eventually benefited by these inventions, although I am not in a position to speak of such matters, beyond that I have always taken an interest in the physical sciences. However, I have just constructed a miniature telephone, so small as to fit, unperceived, into the external

auditory meatus; and with this stuck in my ear, I have been amusing myself this evening by listening in my kitchen to some songs sung by a friend shut up in my attic, my friend singing to a telephone in the attic connected by a wire down the staircase with the miniature telephone concealed in my ear in the kitchen. Here I was enabled to appreciate with relish his feeling rendering of "God Save the Queen", with a *libretto* variations, by means of an instrument no bigger than the plug of wax which often occupies the auditory meatus; and as the wires coming out of my ear were so extremely fine as to be invisible except on the closest inspection, nobody could have observed that I was in telegraphic communication with anybody. My experiment proves that a telephone may be constructed of such insignificant dimensions as to be tucked completely out of sight, and yet to answer its purpose perfectly well; and I cannot help fancying that the discovery of this fact may eventually serve in some measure to pave the way for the construction of a serviceable—that is to say, an inconspicuous—sound-augmentor. It is well known that deaf persons dislike extremely to use any apparatus which shall render public or obvious their infirmity—such, for example, as the ordinary ear-trumpet; and, so far, one of the extremities of a serviceable apparatus may hereby perhaps have been obtained. What remains to be devised is a receiving apparatus of such sensitiveness that the voice spoken at a distance from it may be received by it in a transmissible shape; and such an apparatus might be placed on the patient's lap, or carried in his hand, connected by the minute wires with the invisible telephone stuck in his auditory meatus. But the microphone, I find, will not serve for that; however, it is quite possible that, sooner or later, some such contrivance may eventually be devised.

P.S.—I would recommend my contrivance as a convenience in auscultating stone in the bladder, by the microphonic catheter of Sir Henry Thompson.

BALMANNO SQUIRE.

#### SALTS' DRESSING-CASE.

MESSRS. SALT and SON of Birmingham have submitted to our examination an extremely neat and portable case of dressing-instruments, specially designed for the waistcoat-pocket, and containing scissors, forceps, two probes and director, caustic-holder, two bistouries, Syme's knife, and tenotomy. The case is made of aluminium, and the engraving is drawn to a scale of about three-fourths actual size. The instruments, although inclosed in so small a case, are all large enough to be really useful, and are sufficient in variety to meet all ordinary requirements of the general practitioner. Many so-called "pocket-cases" are of such bulk and weight as to be anything but comfortable companions. This, although really practical for everyday use, may almost be carried in the waistcoat-pocket.

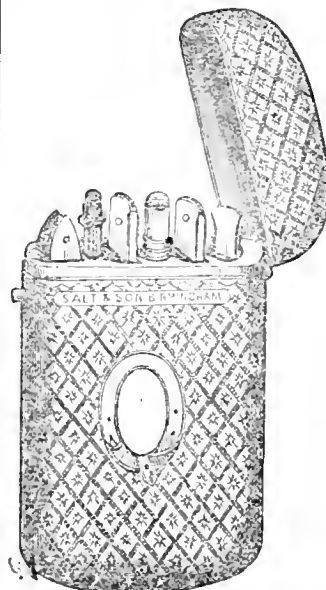

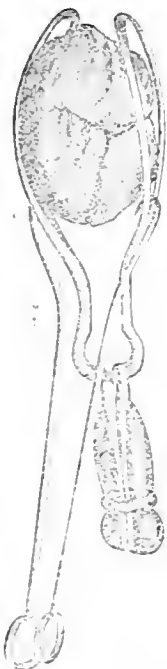

The list of instruments includes, it will be seen, all that are most commonly needed. The instruments commonly made for pocket-cases are unnecessarily bulky. A small knife will do a great deal of cutting; and some of the best surgeons have for many years used a little waistcoat-pocket knife (Pollock's knife) to do all their daily needs.

#### TUPELO-TENTS.

SIR,—In your issue of the 5th instant, you printed a description of a new kind of dilating uterine tent, made from the root of the tupelo tree, a sample of which we had the pleasure of submitting for your inspection. We have been at considerable trouble and expense in introducing these tents into this country; and should feel much obliged if you would permit us to state, through your JOURNAL, that our arrangements are now complete, and that we are in a position to supply them to any of your readers.—Obediently yours,

SALT AND SON.

21, Bull Street, Birmingham, June 11th, 1878.

BRITISH MEDICAL ASSOCIATION:  
SUBSCRIPTIONS FOR 1878.

SUBSCRIPTIONS to the Association for 1878 became due on January 1<sup>st</sup>. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, JUNE 29TH, 1878.

PRISON DIETARIES.

IN no place so suitably as in a prison can we apply to practice the determinations of recent science regarding the bearings of diet on work. Indeed, distributive justice demands that these accurate scales, rather than the rougher machinery of experience, should be made the basis of the calculations according to which our unfortunate dependents are fed. There are three parties whose rights have to be weighed: the law, which demands that the life should be really penal; the prisoner, who has a claim to be restored to society in no worse condition than that in which he left it, and that his punishment should be definite and not greater than contemplated in the sentence; and the ratepayers, who require that the expenses should be kept down to the minimum consistent with other rights. It is obvious that mere experience and observation can never answer the questions raised in the endeavour to satisfy these claims. None of the parties concerned can be justly experimented upon; observations are collected from such a number of sources, and require correction by so many special circumstances of individual mental constitution and sphere of inquiry among the reporters, that they resolve themselves into mere personal authority; so that the *a priori* reasonings of science are perforce the bases of decision. We are glad to see that the Committee appointed to inquire into the dietaries of the prisons in England and Wales, subject to the Prison Acts of 1865 and 1877, have recognised this fact in printing the laborious analyses by Messrs. Gover and Briscoe, where each separate article of food is resolved into its component parts of nitrogenous matter, carbohydrates, fats, and mineral matters, and the totals compared with the expenditure of the body in generating force during rest and work. We are glad also that they recommend an uniform dietary for the prisons within the area of inquiry; and we hope that this dietary will not be merely set forth as a model, but enforced on each of the establishments included. The only arguments for variation are, first, the differing proportions of prisoners guilty of serious or light offences; and, secondly, the prices of food in various localities. To the first, a sufficient correction is afforded by the classification of diets according to the duration of imprisonment; and, if any place be happy in having a large proportion of its offences of a light character, punishable by short imprisonments, rendered cheap by the infliction of bare existence diet, by all means let it get the reward of its virtue and vigilance. The price of provisions at various places is a more serious objection to uniformity; but here it is to be observed that it is not the more bulky portions of the fare which differ greatly, but such things as salt, pepper, onions, and cocoa, according to the comparative table in the report alluded to. And these striking variations must, we think, admit of some compensating explanation; for there seems no commercial reason why Oxford, for example, should be paying 9s. 4d. per cwt. for salt, which at Birmingham costs but 1s. 8d.; or why the first should get its pepper at 7d. a pound, which in Cornwall costs 3s.

Of the dietaries suggested for local adoption by the Home Office, that of 1843 has been more generally followed, with variations, than that of 1864. This is apparently not by reason of its freedom from defects (for it is reported to be "strangely anomalous and eminently unsatisfactory"), but from its greater simplicity in the classification of

prisoners. This simplification of the otherwise better dietaries of 1864 the present reporters propose to attain by the ready expedient of rating women and children along with men not performing hard labour, the effect of which is to reduce the classes of diets from twelve to four, and thus to lighten greatly the duties of the administrative departments, and to avoid the waste and confusion arising from a multiplicity of dietaries.

Simplification, by reducing the number of classes, enables the proposers of the new dietaries in the recent report to obviate one of the impediments to the adoption by prison authorities of the Home Office scale of 1864; namely, the more extended use of fresh vegetables, which rendered that scale troublesome in application. The dietaries of 1864 are a great improvement in this respect on those of 1843; but, as before stated, the intricacy of their subdivisions has made them unpopular with officials. The alternative substitutes of greens, parsnips, and leeks in place of potatoes are judicious; but we question whether rice or "preserved potatoes" can be so regarded. The latter can hardly be ranked as antiscorbutics on land; and weight for weight, when cooked, they are too watery to replace the genuine fresh article in nutrition.

A noticeable feature in 1864 was the considerable reduction of the quantity of meat advised in 1843 for those undergoing hard labour—from 11½ oz. to 7½ oz. (chemical reckoning) per week. This seems to have answered well in the few establishments which adopted the last dietaries, and it has consequently been carried a little further by the suggestors of the new scale. It is certain that farinacea and other vegetables supply a temporary fund of daily force; and hard labour, though conventionally called "hard", does not so wear out the muscular and nervous systems as to require their extraordinary renewal. It is well pointed out by Mr. Gover that imprisonment, as now generally conducted, is a condition more or less akin to that of physiological rest. From the moment the gates close upon a criminal, there is a tendency in most cases to lessened waste of tissue, and he lives, in fact, less rapidly than before. He is free from the worry and anxiety entailed by the struggle for existence, by desire and passion and their inevitable reactions. He spends nine hours out of the twenty-four in bed; and, to judge from his manner and appearance, his mental peace is untroubled by any pains of the conscience. He is qualified for spare living by every possible circumstance—except his tastes; and these doubtless are in favour of indulgence. Is it necessary to gratify them in order to keep up his health? Our own experience of individuals inclines us to say "No", and to think that the health is the more improved the more complete the change; that is to say, that the most luxurious derive most benefit from being restricted to spare and unstimulating food, while the hard-livers do not bear so well a diminution of their bill of fare. This opinion is strengthened by the remarkable fact that in the agricultural districts, where little meat is habitually eaten, the prisons find it expedient to supply it on a more liberal scale than in the manufacturing towns, where the working classes in freedom consume a larger proportion of nitrogenous food. We cannot for a moment sanction, as an objection to a dietary, that a prisoner does not like it. The intention is to subject him to a discipline he does not like, and there is every reason for making his alimentation a part of this discipline. Perhaps the government of Nineveh may be accused of over-refinement when (as we learn from Mr. Smith's translations of the tablets) the prisoners were obliged to drink the water of the sewers; but the principle must not be overlooked, that a criminal must be fed on "the bread of affliction", provided always that he does not lose weight to an extent inconsistent with health.

A permissory substitution for meat of fish, beans and bacon, and peas, is capable of effecting a great saving. The prisoners will not look upon it as a luxury, and yet the variety is good for their digestion. But, as a whole, we cannot congratulate the ratepayers on the promise of any beneficial change in the expenses of maintenance in the report we have just been reading; indeed, the reporters expressly declare that they have viewed the question of cost as of secondary importance.

This is unfortunate; for, with the materials they can command, they might have given advice of great value, which would facilitate the reception they must expect from county boards.

The correction of idleness and misconduct during confinement by reduction of food is a very serious matter. The habitual diet ought to be as low as is consistent with health; and we must understand that, in reducing it, we are administering corporal punishment. The victim will lose flesh and power of resistance as infallibly as he loses leather in a flogging, and he will certainly be put to pain. But let society beware of discarding in too great a hurry survivals of more barbarous states of civilisation, till it is proved that they are not needful safeguards. The reporters are of opinion that, to secure the purposes of punishment for prison-offences, the plan of reducing the diet to a scale as low as one pound of bread *per diem* should be continued. The worst of all corporal punishment is, that it cannot be fairly graduated to the offence; for, while three days' bread and water is not too much to act as a deterrent to very moderate offenders, to continue its infliction over that time results in injury beyond what is designed. It may be suggested, however, that the three days' fast can easily be repeated over and over again after an interval, just as floggings are administered in moderate doses weekly or fortnightly to brutal offenders. Thus the strong moral influence of anticipation is brought into play, whilst danger to health is not incurred. The power of the stomach as an implement of education, moral and intellectual, is the subject of a familiar quotation from an observant poet, and it is a pity to surrender any power left us of improving the manners of criminals.

#### OBLITERATIVE ENDARTERITIS.

THE almost universal part played in pathology by obliterative arteritis, its mode of origin and real nature, are, or have been until lately, ignored by British pathologists, or, if seen in some cases, they have been totally misunderstood. The facts are not new, but they are not recognised, perhaps because workers at histology limit themselves too much to a narrow field of special observation without preparing themselves by wide study of changes as they occur in all the tissues of the body, in inflammations, in new formations and tumours of all kinds. Apparently, MM. Cornil and Ranvier were the first to describe this change. They say, "Dans les plaies, dans les ulcères, et dans les phlegmons chroniques, il n'est pas rare de rencontrer, sur les coupes minces faites pour l'examen microscopique, des artères dont la tunique intime a végété de manière à oblitérer complètement le calibre du vaisseau" (*Manuel d'Histologie Path.*, pp. 554-5). But we owe to Friedländer and Köster the first precise descriptions of the condition, their observations having been published almost simultaneously at the beginning of 1876. (A paper on the subject, by Dr. Friedländer, was noticed in the *BRITISH MEDICAL JOURNAL* of March 18th, 1876.) They showed that in all growths, whether inflammatory, tubercular, syphilitic, sarcomatous, or other, it was not uncommon to find the lumina of the vessels narrowed by a small-celled circumscribing or laterally placed growth of embryonic tissue, which was accompanied by a similar infiltration of the outer coat in a more advanced state of organisation, and by a less degree of affection of the middle coat, which tended to lose its distinctive muscular character and become fibrous. They compared these changes to those which take place in the so-called organisation of thrombus, and held that the growth from the inner membrane was formed from elements which had migrated from the vasa vasorum. These observations were all the more opportune, as in these recent years we have had two forms of obliterative arteritis described, to each of which specific characters have been assigned and considerable pathological significance has been claimed for them. We refer to the arterio-capillary fibrosis of Gull and Sutton, and the syphilitic arteritis of Heubner. It is true that, so far as the renal arterioles were concerned, the facts brought forward

by Sir W. Gull and Dr. Sutton were not new, but our want of knowledge at that time as to the true nature of the process made them assign to it an importance which it by no means deserves. If they had known that the coats of the vessels universally take part in the surrounding connective tissue changes, they would not have ventured to find in their arterial thickenings evidence of a general primary disease of the blood-vessels. Other observers have failed to confirm their assertions that these changes are further distributed than surrounding processes fully account for. Most of the cases of so-called syphilitic arteritis also come under the same category of secondary processes presenting no anatomical distinctive features. The changes described by Oedmansson in the umbilical vessels, and Fränkel in the placenta of syphilitic foetuses, are now known to present nothing characteristic; and identical appearances have been described by Mr. Lawson Tait in non-syphilitic placenta (*Transactions of the Obstetrical Society*, vol. xvii). The same remark applies to the vessels figured by Dr. Batty Tuke (*Journal of Mental Science*, October 1874) as found in the brain of an insane patient who had had syphilis; while Friedländer goes so far as to say that the syphilitic arteritis of Heubner is "a typical obliterative arteritis, which presents no specific syphilitic peculiarities whatever, and, moreover, is in no way etiologically limited to syphilis alone".

The syphilitic arteritis of Heubner differs in one important feature from all the other affections we have alluded to in being an independent affection of the vascular system, that is, not necessarily dependent upon gummatous growth around. It is true that there is no difference between the changes that occur in the middle cerebral artery, for instance, which lies imbedded in a gummatous mass involving neighbouring parts, and that which is not so surrounded; but it is not the less a striking feature, that this disease may, and does frequently, arise primarily in the coats of the vessel, and shows no tendency to involve the surrounding parts, as in the case related below. Heubner considered it a "gummatous" affection of the vessel, originating in the intima, due to irritation by the syphilitic virus in the blood and growing by proliferation of the epithelioid lining of the vessel, and secondarily giving rise to changes in the muscular and outer coats from migration of cells out of the vasa vasorum.

Dr. Paul Baumgarten of Königsberg, already known by his contribution to our knowledge of the process of organisation of thrombi, has recently published some further observations (Virchow's *Archiv*, Band lxxiii, Heft 1) on syphilitic arteritis, and endeavours to settle the questions at issue between Heubner and Friedländer. On the general subject of endarteritis, he is completely at one with Friedländer, except as to the part played by the epithelioid lining; he finds that, in endarteritis artificially produced by ligature, the epithelioid lining first undergoes proliferation, and that the changes in the outer coats occur later and by migration of cells from the vasa vasorum. He relates a case of primary syphilitic arteritis in a man who died of general paralysis of syphilis, and in whose brain the arteries at the base were "generally thickened and white coloured, both middle cerebral arteries being changed into thick greyish white cords, no basal meningitis, and indeed no affection of the basis cerebri et crani". Microscopical examination of these vessels showed an indifferent non-vascular embryonic growth in the lumen; and in the adventitia a vascular, partly caseating, round-celled formation, containing giant cells, and encroaching upon the middle coat so far as in one case to be continuous with the growth in the intima. He considers the periarterial formation to present the characters of gumma, but the internal growth he regards as a non-specific indifferent production; so that he agrees so far with Heubner as to admit the disease to be gummatous and to deserve a specific title; but so far as the endarteritis is concerned, he considers it a non-specific change in a strictly anatomical sense. Reasoning from the analogy of his observations on artificial arteritis, he is quite willing

to accept Heubner's statement that the process commences by proliferation of the epithelioid lining, and that the changes in the outer coats are due to the migration of cells out of the vasa vasorum; but according to him, it is this latter growth only which takes on the characters of "gumma", the internal new formation retaining its indifferent character, and behaving throughout like ordinary granulation tissue developed in the same situation under non-specific influences. This view is not to be confounded with that held by some English observers, especially Dr. Davidson of Liverpool, who contends that the periarterial gummatous formation precedes the obliterative process, which latter, according to him, takes place by the organisation of a thrombus formed by the partial occlusion of the vessel through the pressure of the external growth—a mode of production already long ago put forward by M. Ranvier as that in which tubercular obliteration of the blood-vessels is effected.

#### LONDON SCHOOLS, TEACHERS, AND FEES.

WE mentioned lately the negotiations for increasing the fees of the London medical schools. These have now been carried on to the point that the majority of the London medical schools have agreed to raise their fees to the extent of about twenty-five per cent. The grounds for that increase are very well known and apparent on the surface. Medical courses are more numerous; medical teaching covers a larger field of study; its methods are more thorough and practical, and include practice in doing as well as seeing, and the study of objects of demonstration and of principles instead of merely theoretic discourse. The cost of the increased staff and the increased labour and time devoted to teaching by the staff has grown so much, that if the two or three dozen lecturers and tutors of each of the dozen metropolitan schools are "to live", the price of the whole curriculum must be raised.

But are they to live? It is a pity that this question was not discussed first. For ourselves, we shall have no hesitation in saying—what Talleyrand said to the gentleman who prefaced his apology for a questionable proceeding by explaining that he must live—the necessity is not clear. Is it a good thing, or is it not rather a bad thing, to keep up a dozen schools in London, each with its show of completeness, its staff of lecturers on botany, chemistry, materia medica, anatomy, histology, comparative anatomy, hygiene, and so forth, besides the staff of clinical teachers?

Such lectureships and such an apparatus of teaching have no natural or necessary relation to a hospital. Private rivalry and considerations of professional interest, the love of teaching, the tendency to follow precedents, the desire and the advantage of disciples, have contributed to attach a completely equipped medical school to every hospital—complete on paper, in skeleton, and commonly marked by an honest effort to supply reality to the scheme. But at what effort and what sacrifice of efficiency is this dismal pretence often maintained! What tedious apprenticeship of unwilling lecturers, to whom the only way to a hospital appointment is through the portal of a temporary professorship on a subject of which the lecturer often knows little and for which he cares less! On the one hand, great hospitals, such as the London, have magnificent clinical material running to waste, because the school cannot be brought successfully into competition with the more wealthily endowed or academically favoured schools of St. Bartholomew's, Guy's, University College, or King's College. On the other hand, University College Hospital is overpopulated with students, who find inadequate clinical material. There is more than enough scientific power for one or two great scientific schools, with clinical facilities at all the hospitals; at present, that power is largely wasted, dispersed, and ill paid.

The metropolitan student is badly off for teaching, as compared with what he ought to be. The fees already are high; and, after he passes all the examinations of all the colleges and gets all the diplomas, he is not allowed to call himself Doctor, and he is at a disadvantage as compared with the student of every other metropolis.

The hospitals of London are among the best in the world; but the same cannot be said of the medical teaching. Everybody undertakes to teach; and a large proportion of the teachers have not even the elementary qualities required for it—neither clearness nor application to the theory or practice of teaching, nor systematic study, nor method of tuition. We proceed on the supposition that every young aspirant for a hospital appointment is a heaven-born teacher in a great variety of subjects. The aspiration to hospital appointments is a frequent and pardonable weakness of young men of very mediocre attainments indeed and still feeble powers of tuition, but well provided with the financial means of waiting in London for years without income. Such men are dealt with commonly on the hypothesis that they must necessarily possess a heaven-born capacity for lecturing on any subject, and they are employed accordingly to fill up vacancies in succession. Experience, however, shows that it is an error to assume that the possession of such ambition and of a given number of pounds is always coincident with brains enough to study deeply, and application and clearness of intellect enough to teach well in almost any subject. Nevertheless, this is the principle on which a large proportion of the staffs of the metropolitan schools are appointed; and it is in virtue of this arrangement that a dozen schools will now raise their fees for teaching.

In our opinion, the raising of the fees is beginning at the wrong end. The schools need to be consolidated; the scientific teaching put on a higher footing; and, at the end of his studies, the student should be able to obtain a diploma of M.D., like the student of Edinburgh, Dublin, Cork, Belfast, Glasgow, Aberdeen, Galway, or Durham. The shepherds should think a little more of their sheep and a little less of themselves.

A MEETING of the General Medical Council has been summoned for Friday, June 28th, at 2 o'clock P.M., to consider the Amendment of the Medical Acts.

ANOTHER death is recorded this week—at Belgrave, near Leicester—from the accidental swallowing of a quantity of carbolic acid. The man poisoned drank it believing he was drinking out of a brandy bottle. The free use of carbolic acid as a disinfectant causes an immense number of fatal accidents.

It ought not to escape the attention of those who are occupying themselves with the details of the Medical Acts Amendment Bills, that the chemists and druggists are bestirring themselves very actively, although quietly, to "defend the interests of chemists in prescribing", and to procure the repeal of the securities afforded by the Apothecaries' Act against the unlimited generalisation of unqualified practice by pharmaceutical chemists. *Vide the Pharmaceutical Journal* of June 22nd, 1878.

AN inquest was held on Wednesday, before the deputy coroner for Manchester, upon the body of John Pritchard, aged five years, who, two months ago, was playing in the street, when a cat bit him on the right arm with great ferocity and was with difficulty got off the boy. He was taken to the infirmary, and in course of time the wound healed. On Thursday last, he began raving. He was taken to St. Mary's Hospital, when symptoms of hydrophobia appeared, and he was placed under treatment for that disease, and got better; but the attacks returning, he gradually sank and died on Monday. A verdict of "Death from hydrophobia from the bite of a cat" was returned.

DR. DUDFIELD has published a well-reasoned statement, in reply to the allegation, coming from a medical authority, that "the Small-pox Hospital at Fulham is the great focus from which the disease is spread to the neighbouring parishes". Such a statement is one which is always popular and easy to make, but experience has in every instance proved that it is contrary to the fact. Dr. Dudfield shows quite conclusively that it is so in this case. Each poor-house in which small-pox occurs is a badly isolated, badly administered "small-pox hospital", and

becomes a "focus of contagion". It is from the private houses of the poor that infection spreads, and not from well isolated and well administered hospitals, which, on the contrary, offer the surest means of arresting the spread of contagion.

#### THE HUNTERIAN MUSEUM.

THE annual collection of the preparations added to the museum during the last twelve months will be exhibited in the theatre of the Royal College of Surgeons on Tuesday, Wednesday, and Thursday next week.

#### THE CASE OF MR. DODWELL.

WITH reference to the recent report of Dr. L. J. Forbes Winslow and Dr. Winn concerning Mr. Dodwell, whom they have visited at Broadmoor, we have reason to believe that, as he is now declared free from excitement and perfectly sane, the main reason for his detention is that, having been committed as a criminal lunatic, the authorities require a substantial guarantee from his immediate relatives that they will look after him on release and be responsible for his good conduct; but, as they are without resources, they are unable to give any such guarantee.

#### INFECTION IN SCHOOLS.

THE frequency with which infectious diseases are spread by children attending large schools, especially national and board schools, has led to several plans being adopted for counteracting the evil. The most recent is one somewhat similar to that recommended by the Society of Medical Officers of Health at the instance of Dr. Dudfield; but the form to be filled up is much more simple, and is the production of Dr. Elliot, the Medical Officer of Health for the Carlisle Urban Sanitary District. The form consists of a small slip of paper whereon are printed the name of the school, a heading for the name of the scholar, the address, the name of the medical attendant, and the date of the first day of absence. To these might have been usefully added another line for the "supposed disease". There is also a counterfoil, and the forms are bound up in a small book. With the book Dr. Elliot sent a circular pointing out to the teachers of large schools that their own interests are involved in an early notification to the medical officer of health of the existence of cases of infectious diseases, as by early notice the disease may often be prevented from spreading, and the breaking up of these schools frequently avoided. As Dr. Elliot says, "a threatened pestilence, like a fire, may be quickly stamped out if promptly and skilfully dealt with; but, if neglected for a time, it quickly spreads, and can only be dislodged at a great cost, it may be, of both money and life". The mode of forwarding the information is not stated in the circular; and the medical officer would, therefore, probably expect the notice to be sent by hand, or post-paid through the post. This seems somewhat of an oversight, as it is found in practice that teachers will not pay the postage, or take the trouble to send the notice to the sanitary officer if at any distance away; so that the plan adopted at Hackney by Dr. Tripe, of using post-cards with his name printed thereon, with the following words on the other side, "case of infectious disease", "name", "address", and "supposed disease", with blanks to be filled up, seems decidedly preferable. The difficulty of obtaining information of the occurrence of these cases has induced medical officers of health to ask it from district visitors, clergymen, School Board visitors, and others, often with very good results.

#### CAUSES OF INFANTILE MORTALITY.

IN consequence of the great mortality at Macclesfield amongst infants, and a statement which was made in open court at a coroner's inquest that there was a large amount of child-murder in the borough, a committee was appointed by the Town Council "to confer with the medical profession, the health and sanitary officers of the corporation, and such others as they might deem fit, on the subject". After making due inquiry and taking evidence in the matter, the committee reported

that there was nothing to show that child-murder or criminal neglect occurred in the borough; but there was no doubt that the infant death-rate in Macclesfield is considerably in excess of the average throughout England, and that most of the causes of the excessive mortality are preventable. In 1876, the death-rate amongst infants under one year was as high as 21 per cent. of the registered births, having been above 19 on average of some years, which was attributed by the Committee to the following causes: 1. To the lack of maternal care of children, arising from mothers returning to their work too soon after confinement; 2. To improper feeding and exposure; 3. To the too frequent use of narcotics and soothing medicines; 4. To the ignorance and negligence of parents in not seeking promptly proper medical advice for their children; 5. To constitutional and hereditary causes arising from the immorality of parents, etc.; 6. To lack of personal cleanliness in neglecting the daily washing of children; 7. To residence in unhealthy and ill-ventilated houses; 8. To overindulgence in drink by the parents. To these we may add the not using the means of ventilation already provided by open doors and windows; by allowing unwashed bedding and other clothes, including rags, to remain in the shut-up bedrooms; and by overcrowding. This last cause of infantile mortality is too often lost sight of, as it was in this investigation, although it is a frequent cause of diarrhoea and general ill-health. The effete matters given off from the lungs and skin of a number of individuals crowded into one apartment, which is kept shut up for warmth, afford a very suitable atmosphere for the induction of tubercular affections and the spread of zymotic diseases. Dr. Bland, the medical officer of health, in his report for 1877, says that this mortality was much reduced in consequence of the moderate temperature of the summer and consequent diminution of deaths from diarrhoea, and of the large number of wet open midden-steads which have been abolished, and covered ash-pits substituted in their places. At Hanley, where the infantile death-rate was as high as 193 per 1,000 registered births, Dr. Swift Walker attributes the mortality to precisely similar causes; indeed, almost all medical officers of manufacturing towns are agreed in this matter. The sale of opiates, such as Godfrey's cordial, should be forbidden, except under a medical man's order, as no regulation less stringent will prevent the mortality arising from the continuous drugging of infants.

#### UNQUALIFIED PRACTICE.

DR. HARDWICKE held last week an inquest, in the course of which two of the prominent evils of the present system of unqualified medical practice by prescribing chemists came under notice. It will be observed that, as the chemist chose to call his shop a "medical hall", the poor people were confirmed in the common delusion that a pharmaceutical chemist is a person possessing professional skill in the diagnosis and treatment of disease; and moreover, an unworthy member of the medical profession assisted in maintaining the delusion and covering its results, by appending his signature to the death-certificates of the chemist's deceased patients. Both evils are rampant at the present moment, and it is these cases especially which it is desirable to meet by a suitable amendment of the fortieth penal clause of the Medical Act. In the case in question, Dr. Hardwicke held an inquest at the King's Head Tavern, Broad Street, Bloomsbury, as to the death of Alice Seage, aged sixteen months. Mrs. Seage, wife of a goldsmith, of 3, Great St. Andrew Street, St. Giles, said that for some time past the child had been ill. She was first taken with whooping-cough; and the witness went to a Mr. Andrews, who she thought was a medical man, of the Medical Hall, Little St. Andrew Street, St. Giles; and he attended the child, and it got better, but was afterwards taken ill with measles. On Saturday, the child grew worse, and her husband went for Mr. Andrews, who said that he would come over in a few minutes. Instead of him, a gentleman, who was the worse for drink and who could scarcely speak, came, and said that all the child wanted was a little powder on the tongue. Her husband told him that he was not in a fit state to prescribe, and he should not allow him, and ordered

him to leave the house, which he did. After the death of the child, she went to Mr. Andrews, who gave her the certificate of death. She saw him write it. It was as follows: "Alice Seage, aged sixteen months. Last saw her on the 15th of June, at 3, Great St. Andrew Street, St. Giles. Primary cause of death, measles; secondary cause, pneumonia. Duration of illness, two days. Joseph L. Kingston, L.R.C.P. Edin., of 1, Little St. Andrew Street, St. Giles." The witness took it to the registrar. She did not know Dr. Kingston, by whom the certificate was supposed to be signed. Mr. Faulkner said that he was the registrar of the district. He had received the certificate of death of the deceased, and also six other certificates like the one produced. He had never seen Dr. Kingston write. Dr. Joseph Linsey Kingston said that he was registered in 1865. No. 1, Little St. Andrew Street, St. Giles, was a medical hall. The place was not in his name, but in Mr. Andrews's, who was studying for the profession. The witness saw the child three times and signed the certificate. Mr. Andrews also signed it, because the witness did not know the name of the child. Mr. George James Andrews, of 4, Castle Street, Leicester Square, said he kept the Medical Hall, Little St. Andrew Street. He was a chemist, but was not qualified, and had been a pupil of Dr. Kingston for sixteen months. He had not attended any lectures, nor had he walked the hospitals, although he had been connected with the medical profession for twenty years. He was paying Dr. Kingston 9s. per week for reading up, and intended to enter the Charing Cross Hospital. He attended the deceased, who was at first suffering from whooping-cough, and afterwards from measles. He last saw her on Saturday, just before she died. Dr. Kingston was in a hurry to go somewhere, and left the certificate of death signed, so that the witness might fill it in. The jury returned a verdict, "That the deceased died from inflammation of the lungs after measles; and that they were of opinion that it was highly improper that George James Andrews, acting as a chemist and unqualified, should be allowed to attend patients and to procure certificates of deaths signed by a qualified practitioner for the purpose of registering deaths". It will have been noticed that Mr. R. H. S. Carpenter, who has rendered considerable professional and public services during the last year or two in this matter by enforcing the law and bringing the necessity for amendment of some of its provisions under the notice of Mr. Cross and the Duke of Richmond and Gordon, considers that the provision in Lord Ripon's old Bill of 1870, which has been adopted *en bloc* by the Medical Reform Committee as the Association Bill (or Medical Act Amendment Bill No. 2), is still more defective in this matter than the amended clause in the Duke of Richmond and Gordon's Bill. He expressed that opinion in a letter addressed to our members last week in these columns by the application of an adjective of unusual and, we think, regrettable strength; but we feel sure that Mr. Carpenter and his colleagues in the Medical Alliance and Defence Associations will find that the promoters of Bill No. 2 will be most glad to concert with them such further amendments in committee as may serve the purpose of promoting public and professional security.

#### HAMMOCK STRETCHER FOR INVALID TRAVELLERS.

ON Friday, June 21st, 1878, by the kind compliance of the managing director of the London, Chatham, and Dover Railway, Mr. Richard Davy had the opportunity of practically testing his improved hammock stretcher. The patient was an ex-policeman, suffering from disease of his pelvis and psoas abscess, the result of a fall received in the discharge of his duty. The distance covered was from the Westminster Hospital to the Royal Sea-bathing Infirmary, Margate. The net hammock was slung on the stretcher by four cords, playing on four India-rubber cylinders, which act similarly to intervertebral discs. The stretcher consisted of two shoulder-poles, connected by two iron cross-bars; this was slung to the roof of the railway-van by two cord pendants. The connection and disconnection of the whole mechanism was effected in an instant. The patient quite enjoyed his transit, stating that he was absolutely free from concussion, and capable of pro-

ceeding any distance under similar conditions. At Margate, two strong good-natured porters (London, Chatham, and Dover Railway) carried the stretcher and patient from the van to his bedside in the infirmary. Mr. Richard Davy will be pleased to show the whole arrangement, and its practical working, to any members of the profession, on Tuesday afternoons, at the Westminster Hospital.

#### BENZOATED ALCOHOL.

WE referred lately to the antiseptic value of benzoic acid and Gruber's recommendation of benzoate of soda, as an antimycotic medicine. Benzoated alcohol is much recommended by Dr. Templeton as a basis of valuable and pleasant antiseptic solution. It is recommended to dissolve half an ounce of the pure benzoic acid, prepared from the resin, in a pint of spirits of wine. Mixed with water, it makes a pleasant, effective, and innocuous lotion-gargle or spray.

#### ANTISEPTIC OSTEOTOMY.

IT will have been observed that the method of operating, especially recommended by Mr. Chiene, Surgeon to the Royal Infirmary, Edinburgh, for deformity of the lower extremities, has already recommended itself to several surgeons. The operation, as first practised by Mr. Chiene for knock-knee, consisted in removing, with antiseptic precautions, by means of a mallet and chisel, a wedge-shaped portion of bone from the internal condyle of the femur, without in any way interfering with or opening into the knee-joint. The two cases which Mr. Chiene thus treated with surprising success were shown at the Medico-Chirurgical Society, and referred to in the *Edinburgh Medical Journal* for September 1877. Since then, Dr. Macewen of Glasgow (*Lancet*, March 30th, 1878), in a similar way and with equal success, removed a wedge-shaped portion of bone from the anterior surface of the femur of a girl affected with a stiff bent-knee; and only lately, Mr. Barwell has described in this JOURNAL (May 18th), how he was able greatly to benefit two cases of almost hopeless deformity by breaking, after almost completely dividing, the bones of the leg in one case, and both leg- and thigh-bones in the other, and then keeping them in position by means of plaster-of-Paris. By similar operations—cutting down on, and either removing a wedge-shaped portion, or completely dividing the bone—much good may be done for many children. When the operation is done antiseptically, the danger is reduced to a minimum, as in the cases above referred to; and, seeing that it will seldom be necessary to open into the knee-joint, it may be hoped that those acquainted with the use of antiseptics will not hesitate to give their patients the chance of escaping from being confirmed cripples. It is but right to add that the practicability of this operation was proved by Mr. Chiene more than a year ago, so that Dr. Macewen can scarcely be justified in looking on his case as "the first of antiseptic osteotomy performed in Britain".

#### ASCENDING NEURITIS.

O. ROSENBACH has been carrying on a series of experimental researches in the Physiological Institute of Breslau, of which the object was to produce peripheral inflammation in nerves in order to study the upward extension of the neuritis and its implication of the spinal cord. This process, which has been affirmed in a number of cases, as is well known, from the results of *post mortem* investigations, Rosenbach expected to be able to produce by the irritation of the nerve-trunk in guinea-pigs. He experimented in fifteen cases on the sciatic nerve; and in six cases on the pneumogastric nerve. He employed sometimes turpentine injection as an irritant, and sometimes he drew a thread through the nerve-trunk. In the first series, he obtained only perineuritic inflammation; in the second, only inflammation, or more correctly speaking destruction, of the parts of the nerve-bundles which were pierced; in no case did even the smallest tendency to an extension of the neuritis to the neighbouring parts or to the spinal cord show itself. He admits that, notwithstanding these negative results, it is possible that, by the employment of other irritants, an irritation with a tendency to extension might be induced. He attributes, however, im-

portance enough to the failures of his experiments to justify the conclusion that the occurrence of ascending neuritis must be considered as seriously in doubt, so far as an affection is meant in which the real peripheral localised inflammation produces the more central affection and does not merely exist alongside of it. He considers it further doubtful, on the ground of these researches, whether that which has been in previously related cases ascending neuritis has been really an inflammation, and not perhaps only a trophic change.

#### SEPTIC AND ASEPTIC FEVER.

ACCORDING to Gentz and Volkmann, in addition to the recognised septic form of traumatic fever, a second kind, an aseptic traumatic fever, must be noticed. It occurs commonly under Lister's surgical dressing, even when the wounds go on healing, without any local reaction, without pain or collection of pathological fluids. Among a thousand carefully and quite successfully treated severe wounds or operations running the usually successful course under the antiseptic method, in about one-third there was no febrile temperature; in the second third moderate increase of temperature; and in the last third marked fever. The rise of temperature in this fever is the only clinical symptom, whilst the ordinarily accompanying symptoms which characterise septic fever are altogether absent. Persons suffering from this aseptic fever, with temperatures up to 102 and 104 deg. Fahr., go about feeling subjectively quite well, and have moist skin and tongue; the quantity of urine is exceedingly large and the chlorides are not diminished; the excretion of urea is increased corresponding to the pyrexia. Even in fever of this kind of long duration, the loss of weight is very slight as compared with that which would occur under similar conditions in septic fever. The aseptic fever occurs in the treatment of wounds even when these heal by first intention; it shows itself much oftener in subcutaneous ulcerations, severe contusions of the joints, and especially in subcutaneous bone-fractures where considerable extravasation of blood or compression of internal parts exists. Thus, of fourteen cases of subcutaneous fracture of the thigh in the hospital, only three were free from fever. In six of these febrile patients, the temperature did not exceed 102 deg.; in five it reached 102.2 to 104.2 deg.; whilst, on the other hand, in subcutaneous fracture of the leg, in about half of the cases observed no elevation of temperature was perceptible. The authors consider the aseptic traumatic fever to be a fever of absorption like the septic, only that in the latter heterologous and poisonous substances are absorbed into the blood, which undergoes a process of dissolution; whilst in aseptic fever there occurs in each an addition of substances which are not to be distinguished from those which are produced by physiological regressive metamorphosis of tissue and physiological products: the more abundantly as these products are formed by crushing or injury, the more intense is the aseptic fever.

#### THE CÆSAREAN SECTION IN A THEOLOGICAL ASPECT.

A MEDICO-THEOLOGICAL question has been lately agitated in the French journals in reference to children extracted by the Cæsarean operation. The performance of the rite of baptism has been hitherto restricted to those children that have presented any signs of life after removal from the body of the woman. This is also the rule in England. In France, the operation appears to have been recently performed as much for the purpose of procuring a subject for baptism, as for the saving of the life of the child. Judging by a case which is reported to have occurred at Champoly, the life of the woman is of secondary importance under these circumstances. A woman named Dumas is said to have died from the Cæsarean operation performed on her by a pork-butcher, under the direction of a priest. There was an inquiry, but it came to nothing. The reclamations of the press and the remonstrances of the profession have had no effect. The sole object of the priest was to have the child removed by extraction, in order that the rite of baptism might be performed on it; and he doubtless selected a non-professional operator from the difficulty of finding a member of the medical profession to assist him in his views. Dr.

Depaul, an eminent obstetric surgeon, in commenting upon the facts of the case, truly states that the conduct of both persons was illegal. Had such a case occurred in England, it would have led to a trial and conviction for manslaughter. In dealing with the theological question, *De baptizandis parvulis*, Dr. Depaul makes a few observations which may be of use to medical practitioners on these occasions. A medical man must not surrender his judgment for the performance of this operation to the dictation of a priest or any other person. If he perform the Cæsarean section, he must perform it on his own responsibility and on reasonable grounds, such as would be sanctioned by professional practice. It is a delicate question whether it should in any case be performed on a living woman, as it might accelerate her death. If performed in advanced pregnancy, within a quarter of an hour after death, the child may be equally removed living. The safety of the woman should in these cases predominate over all other considerations. The operation may cause the immediate death of a woman, and this act of vivisection would not be justifiable merely for the sake of baptising a child which might die immediately after its extraction from the uterus. In France, it is much more common to operate on a living woman than in England; but the English law, which allows a husband to inherit the property of his wife, renders it a necessary condition that the child must be born or extracted while the woman is living. Hence it is to the interest of the English husband to have the child extracted from his wife before her death. Medical men have nothing to do with the theological questions connected with this subject. They are of greater importance in Roman Catholic than in Protestant countries. The text of the law in France is that a child can only be baptised after its birth, and the moment of its birth is indicated by its appearance in the light of day, whether this appearance be the result of natural or violent causes—i.e., by delivery or the Cæsarean extraction. Theologians do not admit that baptism can be performed on the child *in utero* through the abdomen of the mother; and it is a moot point whether, in partial delivery, it can be performed unless the head of the child is presenting. The Academy of Medicine have had this subject under discussion, but they have come to no formal resolution. They discourage the performance of the operation on living women; and, even in reference to the dead, they advise that it should not be performed unless the child is viable, or unless it has reached such a stage of gestation as to enable it to live after its extraction.

## SCOTLAND.

A PETITION in favour of the Habitual Drunkards' Bill is being extensively signed by members of the profession in Edinburgh.

THE Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh have each petitioned Parliament against the passing of the Medical Act Amendment Bill in its present shape; and praying that, as preliminary to further medical legislation, if any further legislation be required, the whole subject be referred to a Select Committee or a Royal Commission.

#### ANDERSON'S COLLEGE, GLASGOW.

THE annual meeting of the Trustees of Anderson's College was held on Monday. The Managers' annual report stated that during the session Professor Bowden had enrolled one hundred and sixty-nine students. It also stated that a gentleman, who had withheld his name, had given a £10 bursary, tenable for two years, in connection with the chair of anatomy. In the minutes of the Inquiry Committee, it was stated that the subject of the proposed removal of the College buildings had been under consideration. Some of the members had thought that the whole of the buildings should be removed, while others were of opinion that any removal should be confined to the medical school. The Committee were of opinion that, before any decision was come to, a Subcommittee should be appointed to meet a

deputation from the popular evening classes and from the medical faculty, with the view of ascertaining whether there was any locality which would be acceptable to all parties interested as a site for the College buildings, in the event of the Trustees deciding that a total removal should be carried out. This recommendation was agreed to.

#### VIOLET POWDER.

In a recent report to the Glasgow Town Council, Dr. Russell, the officer of health, comments on an analysis of three specimens of violet powder made to ascertain whether this article was mixed with arsenic. It appeared that one specimen was pure, consisting entirely of starch; that another was mixed with hydrated sulphate of lime (plaster of Paris); and that the third was mixed not only with that material, but with French chalk. It was evident that plaster of Paris was quite opposed to the purposes for which the powder was intended, being an irritant. The motive for the adulteration lay in the difference of cost of the materials; powdered starch costing 34s. per cwt.; white arsenic, 10s.; fine French chalk, 10s.; and plaster of Paris, 2s. 6d.

#### THERAPEUTIC RESULTS OF EXPERIMENT.

On Monday, the 17th ult., Professor Rutherford communicated to the Royal Society of Edinburgh a most valuable and instructive paper on the action of a large number of drugs upon the liver with reference to their power as cholagogues. This paper, which was the continuation of one published in this JOURNAL some time since, contained the record of a very large number of observations and experiments carried on in his laboratory by Dr. Rutherford, assisted latterly by M. Vignal, in virtue of a grant from the Research Fund of the British Medical Association. These experiments were made with seventeen agents in addition to the twenty-nine which had been previously employed. It was pointed out that the great majority of the conclusions arrived at were in complete harmony with clinical experience; but they had at the same time largely supplemented these results and had given many new agents to the physician, of which some had been already, and others would be still more, taken advantage of. Further, they had proved that, if a purgative did not excite the liver, it lowered the secretion of bile; and it was interesting to note that, while they had discovered many new agents which stimulated the secretion of bile, they had found almost no substance, except acetate of lead and henbane, which directly decreased the amount of bile secreted by the liver. They had carried through these experiments in the face of strong opposition; but they would, nevertheless, be amply rewarded, if they should be found to have substantially promoted the cause of scientific therapeutics. The method of observation pursued—viz., by experiments on living animals—was necessary, in order to supplement the clinical method, which necessarily failed to give the exact knowledge desired by the physician. In the debate which followed, Sir Robert Christison characterised Dr. Rutherford's communication as of the greatest importance, and as one which would hand his name down to a very distant future. Dr. Rutherford deserved the commendation of the Society for his courage in going on, in spite of a sentimental opposition, with his researches; he thought the time would come when the public would wake up from the delusion in which it now rested upon this matter. Sir Wyville Thomson said that, in his opinion, if a man in a public position felt that he had knowledge and nerve enough to perform these experiments for lessening the sufferings and prolonging the lives of men, even though they should involve a certain amount of suffering to the lower animals, he was not only entitled but bound to perform them.

## IRELAND.

#### SMALL POX IN THE BELFAST UNION HOSPITAL.

In the Belfast Union Hospital last week, there were forty-two cases of small-pox under treatment, five fresh cases having been admitted, six discharged, and three deaths having occurred during the week.

#### FEE FOR CERTIFYING A LUNATIC.

At a recent meeting of the Tullamore Board of Guardians, Dr. Barry, medical officer of Kilbeggan Dispensary District, wrote complaining that, although an order had been made by a magistrate allowing him two guineas for examining a lunatic, yet £1 only had been tendered. He declared that, if he were not immediately paid, he would apply to the Local Government Board. The guardians, after some discussion, declined to move in the matter, the clerk being directed not to notice Dr. Barry's communication. The fee for examining a lunatic varies from one to two guineas; but when an order is signed by the magistrates, we believe the guardians are obliged to pay the amount certified for.

#### PAYMENT OF MEDICAL SUBSTITUTES.

LAST week we referred to a resolution passed by the Board of Dundalk Union, that each dispensary medical officer should pay for those who should act for him during his absence, except in case of sickness. Since then, the Local Government Board have intimated to the Guardians that a resolution of this kind would not be binding on them at any future meeting; and have referred them to the provisions of Article twenty-seven of the Dispensary Regulations, as to the course to be taken under the circumstances.

#### LIMERICK WORKHOUSE.

At a meeting of the guardians of this Union, held on the 19th instant, a communication was received from the Local Government Board, in reference to the case of Dr. Meehan, informing them that the Chief Secretary, having gone carefully into the matter, saw no reason for interfering with the decision already arrived at by the Local Government Board, and requesting them to appoint a successor to that gentleman, who had been removed by sealed order. The election of a visiting physician was not proceeded with; but in place of this, it was resolved to elect a second resident medical officer, at a salary of £200 a year, with apartments, but without rations. There were five candidates for this appointment, but only three being nominated—viz., Messrs. Dundon, O'Connor, and McDonnell—the contest lay between these; ultimately, Dr. O'Connor was selected. For the office of non-resident apothecary, at a salary of £100 *per annum*, there was only one candidate—Mr. Furlong—who was elected. This enlargement of the medical staff was urgently required, and we are confident that the change will be conducive of much benefit to the sick poor in the Limerick Workhouse.

#### ACCOMMODATION FOR LUNATICS IN IRISH DISTRICT ASYLUMS.

LAST year, eight thousand one hundred and eighty-three insane poor were returned as being resident in district asylums, but suitable accommodation does not exist in them for that number, there being located in some of these institutions from thirty to forty, and even more inmates, beyond their legitimate complement. The necessity for an increased provision for these classes is undoubted, and to a considerable extent of late has been carried out. At present, additions to various asylums are in process of construction, some being nearly completed; viz., at Cork, for 250 patients; at Killarney, for 120; Waterford, 130; Limerick, 150; and at Mullingar, for 50 hospital beds; besides minor works in other asylums.

THE REV. MR. DODWELL.—Dr. L. S. Forbes Winslow and Dr. Winn have published the following report. On the 21st inst., at the request of the friends of the Rev. Mr. Dodwell, and with the special sanction of the Home Secretary, we visited this gentleman, now confined as a criminal lunatic in Broadmoor Asylum. We found him calm, collected, and perfectly rational. He alluded—as he had done on our two previous visits to him in Newgate—to his alleged grievances, and to the motives which induced him to commit a breach of the peace. He admitted that it was an unwise course of action, but contended that he was driven, by the force of circumstances, to commit the act. We were unable to detect, either from his demeanour or conversation, any symptoms sufficient to justify his detention as a criminal lunatic.

## THE ANNUAL MEETING AT BATH.

THE arrangements for the next annual meeting at Bath are, it will be observed, now complete, and the names of the Presidents and officers of Sections are published. It will be seen that the programme is well filled, including the usual business and scientific meetings, and other arrangements which conduce to a successful meeting. The meeting commences on Tuesday afternoon, August 6th; on Wednesday evening the corporation and citizens entertain the Association at a *soirée*; and on Friday evening the Bristol Branch gives a *soirée* at the Colston Hall. The intervening evening is filled by the public dinner of the Association. Some very interesting excursions will be arranged to the picturesque environs of the interesting city of Bath, and to other places.

## HABITUAL DRUNKARDS.

THE following suggestions for the treatment of criminal habitual drunkards are offered by Dr. John Moore, Medical Officer of the County Antrim Jail, and are likely to attract especial attention just now.

Whereas excessive drinking is a fruitful source of disease, pauperism, lunacy, and crime, it is desirable to prevent its extension and diminish its attendant evils by facilitating the control and cure of habitual drunkards. Any person convicted of drunkenness four times within twelve months should be considered a habitual drunkard. The present method of dealing with habitual drunkards by sending them to prison for short periods fails in its object, and is neither punitive, curative, nor preventative. Short sentences do not permit the effects of the drink to be eliminated from the system, and their discharge tends to break down any moral reformation, should such have been begun. It prevents any system of remunerative labour being carried out in prisons, and it exposes the public to the crimes committed, which otherwise would be prevented. It would be better, in the great majority of cases, to discharge prisoners from the police-cells, when sobered, than the plan at present adopted. This would place them face to face with difficulties, which would necessitate them, in the struggle for existence, to make an effort to help themselves; whereas the temporary home and comforts provided for them in the prison remove the necessity for any such effort. Habitual drunkards should be committed like prisoners under remand, but the remand to be for a period of not less than three months. A certificate from the governor, chaplain, and medical officer of the prison, as to the prisoner's fitness for discharge should be laid before the magistrates previous to such discharge. Habitual drunkards, when discharged, should be so conditionally—as on ticket-of-leave—and be called upon periodically to furnish evidence to the magistrates that they are conducting themselves soberly and orderly. A certificate to that effect from a clergyman, or from three householders, to answer this purpose. This supervision should extend over twelve months. All punitive treatment should be withdrawn, and only the necessary restraints employed. Prisoners might be permitted to reside in registered penitentiaries, but liable to arrest on leaving them before duly discharged. All prisoners earning more, while at work in prison, than would cover the cost of their maintenance should have such sums placed to their credit, to be applied to their use after their discharge, or given to their families in the meantime, if such were dependent on them.

In a statement appended to the suggestions, Dr. Moore says that, in 1876, 2,900 individuals were committed to the County Antrim jail; there being 5,196 committals. Of these committals, 4,138 were for drunkenness and for crimes arising out of drunkenness. He also gives a table, showing that, previously to January 1st, 1876, 162 women and 66 men had been committed twenty times and upwards—the number of convictions in the case of the women amounting to 8,411, and in that of the men to 2,336. Among the women, 15 had been each committed above 100 times (100 to 226); while one man had been committed 131 times. He estimates the yearly loss of wages through committals for drunkenness (to the Antrim jail) at about £15,000; and the expense of maintenance in prison at £7,000. The money earned by prison labour last year was £926.

## THE MEDICAL ACTS AMENDMENT BILL.

THE week has been marked by a curious imbroglío of irritated corporations and conflicting reformers. The Duke of Richmond and Gordon must during the late months, and now more than ever, be reminded of the fable of *Æsop*, which tells the fate of the miller who tried to please everyone when he started out with his son and a beast of burden. To please the General Medical Council, he framed his Bill on lines to which they assented; then, to please the Scottish Universities, he took out of it the clauses which provided conjoint examining boards. To please the English corporations, our Association, the majority of the Council, and the profession at large, he consented, after much negotiation, to restore the clauses which he had taken out; then, to please Mr. Stansfeld, Lord Aberdare, and others, he announced that whatever privileges of title the conjoint boards examination gave should be common to women as well as to men. Next, to please some eminent representatives of corporations which object to women obtaining time-honoured medical titles, he accepted in committee an amendment from Lord Ripon drawn from his old Bill of 1870, and to be found in the text of the present Bill of the British Medical Association (Bill No. 2 in the House of Commons), which makes the certificate of the conjoint boards the registrable qualification. This, however, it has been pointed out, virtually shunts the corporations, since not only will women be refused their titles (which was the object aimed at by the advisers of Lord Ripon and the Duke of Richmond and Gordon), but men will not require, and probably will not purchase, them. Hence further indignation meetings and conferences of all the corporations, and petitions innumerable against a clause which the Duke accepted at the hands of a former chieftain of medical reform, which is to be found in the Association Bill, and in favour of which some hundreds of petitions have been presented. Now the Duke is alleged to be once more willing to restore, at the instance of these fresh remonstrants, what he had changed at the instance of previous remonstrants.

But, when once the work of chopping and changing has gone to this extent, people begin to lose confidence, and ask who are the real leaders in medical reform, and how it is that the "eminent representatives", who are always walking in and out at the Privy Council Office and presenting ultimatums to Mr. Peel, are all at loggerheads and do not seem to know either their own minds or those of their constituents.

Meantime the question of direct representation still awaits discussion, and it may prove to be the trump card played at the last moment.

## RESOLUTION OF ROYAL COLLEGE OF PHYSICIANS OF LONDON.

At a meeting of the Fellows of the Royal College of Physicians of London, on June 21st, the Medical Act Amendment Bill was discussed. The two questions which were specially interesting to the Fellows, and on which their opinion was to be expressed, were the loss of privilege of granting licenses, enjoyed since 1518, to practise medicine; and the granting of a diploma to women.

The loss of the privilege of giving a licence to practise would, it was generally thought, be less felt by the College than by many other bodies; and among other changes which would probably follow, if this Bill became an Act of Parliament, would be some alterations in the existing arrangement of fellows, members, and licentiates; that is to say, those who came to the College would seek honour rather than privilege.

As the second question had been recently voted upon, and seemed to be distinctly agreed upon by the College, the first question was submitted in the following resolution, which was adopted:

"That, in the opinion of this College, the right of licensing to practise physic granted by Royal Charter in the year 1518 should not be withdrawn, as is proposed to be done by the Bill now before the House of Commons, entitled 'The Medical Act (1858) Amendment Bill', inasmuch as the withdrawal of such powers would be prejudicial alike to the public and the medical profession."

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE following alterations in, and additions to, the Medical Act (1858) Amendment Bill, have been proposed by the Council of the Royal College of Surgeons of England.

Clause 4. At end of Clause, page 2, line 38, *add*, as rider, the following: "provided, as regards the first case, that if the scheme of any joint board requires that any persons passing the examinations of the board shall become affiliated to any medical corporation or corporations concerned in the scheme, it shall be the duty of such corporation or corporations to affiliate, as the scheme requires, each such person on his application, and a person so required to be affiliated shall not be registered as a licentiate under the above enactment till he shall have been affiliated by the corporation or corporations."

Clause 8, subclause 7, page 4, line 42, after "(this Act)" *insert* "or which the Council sees fit to accept as testimonials of special esteem on the part of the medical authority which grants them".

Clause 13, preamble, page 7, in line 20, *omit* "superintendence of the"; and in line 23, after "the like" *insert* "and further".

Clause 13, subclause 1, page 7, line 27, after "The" *insert* "medical authorities of each part of the United Kingdom, or, if their scheme so provide, the medical board acting on their behalf, subject to the approval of the"; and after "shall" *insert* "frame and may"; and after "time to time" *omit* words from "cause" to "may" (in next line) inclusive; and in line 33, *omit* "superintendence" and *substitute* "supervision".

Clause 13, subclause 4, page 8, line 2, *omit* words after "examinations" to end of subclause, and *substitute* "with such distinctions (if any) as may be judged proper between the cases of men and women, so, however, that the examinations of men and women be in all general respects equal".

Clause 14, page 8, lines 35 and 36, *omit* the words "practise medicine and surgery", and *substitute* "obtain a qualifying certificate under this Act".

Clause 14, page 8, line 42, *omit* "passing", and *substitute* "commencement".

Clause 16, page 10, line 13, after "registration fee" *insert* "and subject to the other provisions of this Act".

Clause 25. *Omit* the clause.

#### THE UNIVERSITIES OF SCOTLAND.

The following statement has been issued by the Scottish Universities.

I. The *Senatus Academicus* in each of the Universities of Scotland engaged in medical teaching have carefully considered the Medical Act (1858) Amendment Bill, as brought from the House of Lords and ordered to be printed by the House of Commons.

II. They would desire to point out that, during the passage of the Bill through the House of Lords, the principle of the measure as regards the registration of medical practitioners has undergone fundamental change.—1. The Bill as originally introduced, and as read a second time in the House of Lords, whilst providing for the voluntary formation of medical examining boards by the conjunction of the medical authorities, and for the granting by these authorities of diplomas admitting to the *Medical Register* those persons who had passed the examinations of this board, yet reserved to the medical authorities the right to have their diplomas registered on their own examinations, if they were granted in respect of proficiency both in medicine and in surgery.—2. After the second reading of the Bill, amendments were suggested by the Lord President, the result of which would have been to require the medical corporations in each division of the United Kingdom to conjoin to form a medical examining board, and to debar them from conferring diplomas admitting to the *Medical Register* on persons who had not previously passed the examination of this board. The universities in each division of the kingdom were permitted, but were not enjoined, to unite with the medical corporations in forming this conjoint examining board; and their graduates would have been entitled to admission to the *Register*, without passing the examinations of the conjoint board. These amendments were not, however, discussed in the House of Lords.—3. In the Bill as amended on Report, all the medical authorities in each part of the United Kingdom, both universities and corporations, were required to unite in forming a conjoint medical examining board; and no person was to be admitted to the *Medical Register* unless he held a diploma granted by a medical authority, after he had obtained from this medical board a certificate that he had shown himself qualified to practise both medicine and surgery.—4. While the Bill was passing through Committee on recommitment, and on the third reading in the House of Lords, other fundamental changes were made in its registration clauses. According to the provisions introduced at this stage, the diplomas conferred by the medical authorities are no longer to be required for registration, and persons are to be registered as Licentiates in Medicine, Surgery, and Midwifery, on simply producing a certificate of having passed the examinations of the medical board. An important excep-

tion, however, is made in favour of a large class of persons holding colonial and foreign diplomas, who are to be permitted to register without having passed the examination of the medical board, a privilege thus being granted to them which is denied to graduates of the universities of the United Kingdom.

III. Should the Bill, in its present form, become law, the relation of the whole medical profession to the medical authorities would be completely changed. At present, a medical practitioner can be admitted to the *Medical Register* only when he has obtained, after examination, a title or diploma from one of the medical authorities, either an university or a corporation; but, under the Bill, he would not be required to connect himself with any of the medical authorities, nor to obtain a diploma from them, but would be admitted to the *Medical Register* independently of these authorities on a new registrable title specially created for him.

IV. In the opinion of the Scottish Universities, the introduction of such a change would prove injurious, not only to the universities themselves, but to the best interests of the medical profession and of the public. On an average, about two hundred candidates annually receive from these universities the Degree of Bachelor of Medicine and Master in Surgery. These degrees are conferred after a more extended range of studies, and more stringent examinations than would be required from candidates for the new licence to practise. As this licence would, however, be the sole portal for admission to the *Medical Register*, students would thereby be discouraged from attaching themselves to the existing medical authorities, and from applying themselves to the more extended range of studies required from candidates for university degrees, and thus the number of highly educated practitioners would be diminished, and the public interests would inevitably suffer.

V. From the fact that three successive and fundamental changes in the registration clauses of the Bill have been made within the few weeks that have elapsed since its introduction into the House of Lords, it is obvious that the Government have experienced great difficulty in deciding in what direction medical legislation should proceed. From the opposition which is being made in various quarters to the Bill in its present form, and from the great difference of opinion existing in the medical profession as to what should constitute a registrable qualification, it would seem that the subject is not yet ripe for legislation.

VI. The Universities of Scotland would, therefore, deprecate the passing of the Medical Act Amendment Bill during the present session, and would suggest that this and the other Bills for amending the Medical Act now before the House of Commons should be referred to a select committee of the House of Commons, or to a Royal Commission, to be appointed to inquire into the working of the Medical Act of 1858.

A. GRANT, *Principal of the University of Edinburgh.*  
JOHN CAIRD, *Principal of the University of Glasgow.*  
W. R. PIRIE, *Principal of the University of Aberdeen.*

#### PETITION OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE following petition against the Medical Acts Amendment Bill of the Lord President has been presented to the House of Commons by the Royal College of Physicians of Edinburgh.

*Unto the Honourable the Commons of the United Kingdom of Great Britain and Ireland in Parliament assembled, the Petition of the Royal College of Physicians of Edinburgh, under their common seal, humbly sheweth—*

1. That a Bill has passed the House of Lords, and has been introduced into your Honourable House, intituled "An Act to Amend the Medical Act (1858)".
2. That at the time the Bill was introduced into the House of Lords, this College petitioned in favour of it, on the ground that while it amended various of the provisions of the Medical Act (1858), it left in the hands of the Universities and Medical Corporations the power of admitting candidates to degrees and licences, subject to the supervision of the General Medical Council.
3. That while the said Bill was passing through the House of Lords, changes of a most important character were introduced, some of the principal of them at the very last moment, so that the character of the Bill, as affecting the condition of the various licensing bodies, was completely changed.
4. That *inter alia* the Bill provides that a joint board shall be established in England, in Scotland, and in Ireland, and that no one can in future be admitted upon the *Medical Register* until he has passed the examination of one of these boards.
5. That the power of granting licences to practise, hitherto enjoyed by the Royal Colleges of Physicians and Surgeons, will be practically

abrogated, and that hence their professional importance and power of usefulness will be most seriously impaired, if not entirely abolished.

6. That no higher qualification granted by the Colleges of Physicians and Surgeons can be admitted upon the *Register* without the sanction of the General Medical Council, and that there is no appeal against the decision of that body.

7. That the Colleges of Physicians and Surgeons having done much for the advancement of the medical profession, by establishing museums, libraries, and otherwise, and by promoting good feeling among its members, it would be a very serious step to deprive them suddenly of the privileges they have so long enjoyed.

8. That it cannot be said that the establishment of such boards as are provided for in the Bill is necessary in the interests of the public, for it is well known that a very great improvement has, within the last few years, taken place in the examinations of the various licensing bodies.

9. That this Bill, should it become law, would call into existence a new class of medical practitioners, merely holding a certificate of qualification from a board, and not connected with any corporate body.

10. That should it appear to your Honourable House that changes are required in the organisation of the medical profession, your Petitioners would humbly suggest that, previous to further legislation, the whole subject should be inquired into deliberately, either by a Select Committee of your Honourable House or by a Royal Commission.

May it therefore please your Honourable House to take the above premises into your consideration, and to take such steps as may prevent the Bill in question from becoming law.

And your Petitioners will ever pray.

Signed and sealed in name and by authority of the Royal College of Physicians of Edinburgh, the twentieth day of June, eighteen hundred and seventy-eight years.

ALEXANDER PEDDIE, M.D., *President*.

#### PETITION OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The following has been presented by the Royal College of Surgeons of Edinburgh.

*Unto the Honourable the Commons of the United Kingdom of Great Britain and Ireland, in Parliament assembled, the Petition of the Royal College of Surgeons of Edinburgh, under their corporate seal, humbly sheweth—*

That a Bill has been introduced into your Honourable House, sent down from the House of Lords, intituled "An Act to Amend the Medical Act (1858)".

That that Bill, amongst other matters, deals with the question of the licence to practise medicine and Surgery, and the registration of medical practitioners, and in doing so introduces a completely new system, which virtually disfranchises all the licensing medical authorities of the Kingdom, and deprives them of that licensing power which many of them have enjoyed for centuries, under Royal Charters.

That that licensing power has been exercised, and is still exercised in such a manner as to promote medical science, and to benefit the public and the medical profession.

That the licensing bodies have been careful from time to time, and more particularly since the passing of the Medical Act, 1858, to alter and modify, as circumstances seemed to indicate, and as recommended by the General Medical Council, their curricula of study, and also their tests by examination, which have been rendered more extensive, more practical, more searching, and in every way more efficient.

That the large proportion of rejections at their examinations, averaging about one-third of those examined, as ascertained from published official tables, testifies that no undue lenity has been shown by the licensing bodies generally.

That as the result at the present moment, the status of the medical profession is very high, and the general body of medical practitioners, in town and country, whether in private practice or in the public service, are so well trained, well informed, and skilful in their profession, as to deserve public confidence.

That while it was desirable that in an amending Bill provision should be made for preventing any person obtaining admission to the *Medical Register* who had not been educated and tested in all the branches of medicine, including medicine, surgery, and midwifery, there was neither necessity nor expediency for abolishing all the old licences, and for establishing, as the Bill proposes to do, new licences in which the names of all the licensing bodies are ignored (their diplomas being set aside and declared unregistrable), and with the granting of which these bodies will, if the Bill be passed, be only very indirectly connected.

That in past times, as at present, the connection of the licentiates with the respective bodies from whom they obtained their licences was

a beneficial connection, and had a tendency to maintain the character of the profession, and that the dissociation of the licentiates from the medical authorities seems calculated to have a deteriorating influence on the profession by diminishing a wholesome *esprit de corps*, and by removing the members of the profession from the observation, jurisdiction, and discipline of the respective medical authorities.

That the result of the proposed changes on the medical corporations will be to lower the prestige of these peculiarly British bodies, which give the profession an useful measure of self-government, unknown abroad, and to cripple their resources, which have been employed for no selfish corporate objects, but, after the payment of the expenses of their examinations, have been devoted to the erection of convenient halls for their meetings and for examination purposes, and to the founding of libraries and museums, which have greatly tended to promote the progress of medical science, and have proved not only important sources of instruction to students and medical men, but also sources of both instruction and gratification to the public, who are largely admitted to the benefits of them on liberal terms.

That your Petitioners would further call attention to this circumstance, that by the proposed Bill, Foreign and Colonial degrees and diplomas are to be allowed a privilege which home degrees and diplomas are to be deprived of, and to be registered without the necessity of the holders of them having been obliged to pass as licentiates, and that there is no guarantee that any equivalent reciprocal privileges are to be granted to British registered practitioners who may wish to settle abroad or in the Colonies.

That this Bill contemplates, as already shown, great and fundamental changes, some of the most important of which, it may be stated, have been introduced into the Bill at the eleventh hour, and hastily passed in the House of Lords, without the medical authorities having had time and opportunity maturely to consider them.

May it therefore please your Honours to take such steps as will prevent the Bill in its present shape from being passed into law; and, as preliminary to further medical legislation, to refer this Bill and the other Bills for amending the Medical Act which are at present before your Honourable House, and the whole question in all its bearings, for investigation, to a Select Committee of your Honourable House, or alternatively to a Royal Commission.

And your Petitioners will ever pray.

Signed in name and by authority of the Royal College,  
PATRICK HERON WATSON, M.D., *Preses*.

A petition to the same effect has also been presented by the Faculty of Physicians and Surgeons of Glasgow.

#### THE MEDICAL ACT AMENDMENT BILL (No. 2).

PETITIONS from the following places and persons have been presented in favour of the Medical Act Amendment Bill (No. 2) up to June 20th.

Alton; Aylesbury; Atherstone; Ashton-under-Lyne; Antrim.  
Birmingham (all the hospital staff); Bakewell (Derbyshire); Brecon (2); Bideford (2); Banbury; Bridlington; Brighton; Bourn; Bourton-on-the-Water; Bexley and Bexley Heath; Bournemouth; Bridgwater; Bridgnorth; Barton-on-Humber; Bury St. Edmunds; Birkenhead; Bacup; Brecknock; Bromyard.  
Croydon; Chelmsford; Chester (3); Chesham; Callington (2); Cardiff; Carlou; Chesterfield; Mr. J. Cooper (Cromer); Calne; Crickhowell; Cottenham; College of Physicians (King and Queen's) in Ireland, praying the House not to pass either of the Bills for the Amendment of the Medical Act in their present form, and that they be referred to a Select Committee.  
Dungannon (2); Dukinfield; Droitwich; Darlington; Drs. Darby, Lency, and Whistler; Dover; Doncaster.  
Eye and neighbourhood; East Retford.  
Fareham; Frome (2); Farnham; Fowey; Faversham; Fairfield.  
Glasgow; Gravesend.  
Holyhead; Huddersfield; Hythe; Hereford; Hanley.  
Ilfracombe.  
Knowle (2); Knaresborough; Kingston-on-Thames.  
Lincoln; Llandudno; Leominster; Langport; Lynton.  
Monmouth; Manningtree; Monaghan County; Macclesfield.  
Northampton; North Shields; North of England Branch, President and Council of; Nuneaton.  
Oswestry.  
Penzance; Portarlington; Pontefract.  
Rotherham (2); Ripon; Richmond.  
Southsea; Southport; Shrewsbury; St. Albans; Spalding; Sutton Coldfield; Stamford; Staffordshire; South Shields (in favour of representation of profession in Medical Council).  
Thames Valley Branch (2); Tredegar; Truro; Tiverton; Torquay.  
Wirksworth; Wakefield.  
Yeovil (2).

## ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL:  
NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the Freemasons' Tavern, Great Queen Street, Lincoln's Inn Fields, London, on Wednesday, the 10th day of July next, at Two o'clock in the afternoon.

FRANCIS FOWKE,  
*General Secretary.*

36, Great Queen Street, London, W.C., June 12th, 1878.

BRITISH MEDICAL ASSOCIATION:  
FORTY-SIXTH ANNUAL MEETING.

THE Forty-Sixth Annual Meeting of the British Medical Association will be held at Bath, on Tuesday, Wednesday, Thursday, and Friday, August 6th, 7th, 8th, and 9th, 1878.

*President:* M. A. EASON WILKINSON, M.D., F.R.C.P., Senior Physician to the Manchester Royal Infirmary.

*President-Elect:* R. W. FALCONER, M.D., F.R.C.P., D.C.L., Consulting Physician to the Royal United Hospital, Bath.

An Address in Medicine will be given by HENRY F. A. GOODRIDGE, M.D., F.R.C.P., Bath.

An Address in Surgery will be given by C. G. WHEELHOUSE, F.R.C.S., Leeds.

An Address in Forensic Medicine will be given by DOUGLAS MACLAGAN, M.D., F.R.C.P., Edinburgh.

The business of the Association will be transacted in Five Sections, viz. :—

**SECTION A. : MEDICINE.**—*President:* T. Grainger Stewart, M.D., F.R.C.P. Edin. *Vice-Presidents:* B. Foster, M.D., F.R.C.P.; Thos. Clifford Allbutt, M.D. *Secretaries:* Thomas Cole, M.D., 17, Paragon, Bath; Chas. Albert Hingston, M.D., 3, Sussex Terrace, Plymouth.

**SECTION B. : SURGERY.**—*President:* G. W. Callender, F.R.C.S., F.R.S. *Vice-Presidents:* Furneaux Jordan, F.R.C.S.; W. Stokes, M.D. *Secretaries:* J. H. Morgan, F.R.C.S., 12, Chapel Street, Park Lane, London; J. F. Parsons, Esq., Frome.

**SECTION C. : OBSTETRIC MEDICINE.**—*President:* A. H. McClin- tock, M.D., LL.D. *Vice-Presidents:* James Watt Black, M.D.; H. Macnaughton Jones, M.D. *Secretaries:* Heywood Smith, M.D., 2, Portugal Street, Grosvenor Square, London; A. E. A. Lawrence, M.D., 15, Richmond Hill, Clifton, Bristol.

**SECTION D. : PUBLIC MEDICINE.**—*President:* J. T. Arlidge, M.D., F.R.C.P. *Vice-Presidents:* D. Davies, Esq.; Francis Thomas Bond, M.D. *Secretaries:* F. Vacher, Esq., 35, Hamilton Square, Birkenhead; W. Harling Sissons, Esq., 3, Priestgate, Barton-on-Humber.

**SECTION E. : PHYSIOLOGY.**—*President:* John G. McKendrick, M.D., F.R.C.P. Edin. *Vice-Presidents:* Henry Power, F.R.C.S.; P. H. Pye-Smith, M.D., F.R.C.P. *Secretaries:* R. Shingleton Smith, M.D., Clifton, Bristol; A. W. Fox, M.B., 16, Gay Street, Bath.

*Honorary Local Secretary:* R. S. FOWLER, Esq., 6, Belmont, Bath.

## Tuesday, August 6th.

11 A.M.—Service at the Abbey. Sermon by the Bishop of Bath and Wells.

2 P.M.—Meeting of Committee of Council.

4 P.M.—Meeting of Council, 1877-78.

8 P.M.—General Meeting.—President's Address.—Annual Report of Council, and other business.

## Wednesday, August 7th.

9.30 A.M.—Meeting of Council, 1878-79.

11 A.M.—Second General Meeting.

11.30 A.M.—Address in Medicine.

2 to 5 P.M.—Sectional Meetings.

9 P.M.—Soirée at the Assembly Rooms by the Mayor and citizens of Bath.

## Thursday, August 8th.

9 A.M.—Meeting of Committee of Council.

10 A.M.—Third General Meeting.—Reports of Committees.

11 A.M.—Address in Surgery.

2 to 5 P.M.—Sectional Meetings.

6.30 P.M.—Public Dinner at the Assembly Rooms.

## Friday, August 9th.

10 A.M.—Address in Forensic Medicine.

11 A.M.—Sectional Meetings.

2 P.M.—Concluding General Meeting.

9 P.M.—Soirée at the Colston Hall, Bristol, by the Bristol members of the Bath and Bristol Branch.

## EXCURSIONS.

On Saturday there will be excursions to Longleat, Bowood, Wells and Cheddar, Malmesbury, Berkeley Castle, and (if a sufficient number of excursionists) to the Valley of the Wye.

The Honorary Secretary will endeavour to arrange for gentlemen well acquainted with the locality to accompany the parties on each excursion.

Any information will be given by the Secretary to the Excursion Committee, 6, Belmont, Bath.

Members of the Association will receive cards for the above proceedings, evening meetings, etc., at the Assembly Rooms, Bath.

## ANNUAL MUSEUM.

The Tenth Annual Museum of the British Medical Association will be held at the Assembly Rooms, Bath, and will be open daily from 10 A.M. till 6 P.M., on August 6th, 7th, 8th, 9th, for the exhibition of the following objects :—

1. Latest Inventions in Medical and Surgical Instruments and appliances of all kinds.

2. New Chemicals and Apparatus; New Drugs and their preparations; and New Articles of Diet for Invalids.

3. Drawings, Diagrams, or Models illustrating the Ventilation of Hospitals and Private Dwellings.

4. General Pathological Specimens; with Photographic Models, Drawings, etc., illustrating disease; and Microscopic Pathological Specimens.

The following is a list of the Museum Committee, to any member of which communications, etc., may be addressed. Sections 1, 2, and 3: Dr. Spender, 17, Circus, Bath; F. K. Green, Esq., 3, Gay Street, Bath. Section 4: Dr. Cole, 17, Paragon, Bath; G. E. Lawrence, Esq., Claverton Street, Bath.

## NOTICE TO EXHIBITORS.

Application to be made as soon as possible, at the same time giving a list of objects, and mentioning the space required. Each object to be accompanied by a printed or written description attached to the article exhibited.

All parcels to be delivered on or after July 27th, and not later than August 3rd, and to be removed within three days after August 12th. They must be addressed to Drs. Spender and Cole respectively, at the Assembly Rooms, Bath. All expenses of carriage and all risk to be borne by the Exhibitors. A card bearing the name and address of the exhibitor to be enclosed in each package, ready to be fixed on the outside.

N.B.—Specimens and Instruments which have been exhibited at former meetings cannot be received on this occasion.

All communications to be addressed to Drs. Spender and Cole, as above.

FRANCIS FOWKE, *General Secretary.*

36, Great Queen Street, London, W.C., June 25th, 1878.

## SOUTH EASTERN BRANCH.

THE annual meeting of this Branch will be held at the Greyhound Hotel, Croydon, on Wednesday, July 3rd, at one o'clock; Dr. LANCHESTER of Croydon, President-elect, in the Chair.

CHARLES PARSONS, M.D., *Honorary Secretary.*

2, St. James's Street, Dover, June 18th, 1878.

## BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE annual meeting of this Branch will be held at the Midland Hotel, New Street, Birmingham, on Tuesday, July 2nd. The Chair will be taken by the President, SAMUELSON GANGE, Esq., at 3 P.M.

An address will be delivered by the President-elect, Dr. TIBBIS, of Warwick.

The annual dinner will also take place at the Midland Hotel, at 5 P.M. precisely, for the convenience of country members. Dinner tickets, exclusive of wine, 7s. 6d. each.

JAMES SAWYER, M.D., } *Hon. Secretaries.*  
EDWARD MALINS, M.D., }

Birmingham, June 11th, 1878.

## SOUTH-EASTERN BRANCH.

A MEETING of the Executive Council of this Branch will be held at the Greyhound Hotel, Croydon, on Wednesday, July 3rd, at half-past twelve o'clock precisely.

CHARLES PARSONS, M.D., *Honorary Secretary*,  
2, St. James's Street, Dover, June 18th, 1878.

## NORTH WALES BRANCH.

The twenty-ninth annual meeting of this Branch will be held at the Imperial Hotel, Llandudno, on Tuesday, July 9th, at 12.30 P.M.: President—R. ROBERTS, Esq.; President-elect—WM. JONES, Esq.

The following cases are promised.

Epileptiform Convulsions, with partial Hemiplegia: Recovery. By Dr. W. Williams, Liverpool.

Gangrene of Ascending Colon; Chronic Priapism. By Dr. Roberts, Chester.

Dinner will take place at 3 o'clock. Tickets, inclusive of wine, 12s. 6d. each.

T. EYTON JONES, M.D., *Honorary Secretary*,  
Wrexham, June 18th, 1878.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH.

The annual meeting of this Branch will be held at Neath, on Thursday, July 11th: J. TALFOURD JONES, M.B., President; JOHN I. CUSSELL, Esq. (Neath), President-elect.

Any members desirous of reading papers, etc., are requested to communicate the titles to either of the Honorary Secretaries.

ANDREW DAVIES, M.D.,

ALFRED SHEEN, M.D., } *Honorary Secretaries*.

June 12th, 1878.

## METROPOLITAN COUNTIES BRANCH.

The twenty-sixth annual meeting of this Branch will be held at the Ship Hotel, Greenwich, on Friday, July 19th, at 4 P.M.: President—SEPTIMUS W. SIBLEY, Esq., F.R.C.S.; President-elect—ANDREW CLARK, M.D., F.R.C.P.

Dinner at 6 P.M. precisely. Tickets, 14s. each, exclusive of wine.

ALEXANDER HENRY, M.D.,

W. CHAPMAN GRIGG, M.D., } *Honorary Secretaries*.

London, June 24th, 1878.

## NORTH OF ENGLAND BRANCH.

The annual meeting of this Branch will be held at Hartlepool, on Thursday, July 25th, at 3 P.M.

G. H. PHILIPSON, M.D., *Honorary Secretary*,  
Newcastle-upon-Tyne, June 8th, 1878.

## BORDER COUNTIES BRANCH.

The annual meeting of this Branch will be held at the Crichton Royal Institution, Dumfries, on July 26th, 1878: President—Dr. LOCKIE; Vice-President—Dr. GILCHRIST.

Gentlemen intending to read papers, or to be present at the dinner, are requested to give notice to either of the Secretaries.

R. MACLAREN, M.D., Carlisle,

JOHN SMITH, M.D., Dumfries, } *Honorary Secretaries*.

## REPORTS OF SOCIETIES.

## CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 24TH, 1878.

GEORGE W. CALLENDER, F.R.S., President, in the Chair.

*Sequel of a Case of Chylous Discharge from the Leg.*—The PRESIDENT communicated for Dr. DAY the points in this case, which had been recorded in an early volume of the *Transactions of the Clinical Society of London*. Nine years had passed since the earlier report before the patient had died from exhaustion. Dr. Wickham Legg had examined the body, and Dr. Gowers had examined the tissues microscopically. The case was one of lymphatic elephantiasis.

*Erythema, with subsequent Exudation and Crusting, allied to Herpes.*—Dr. SANGSTER exhibited the patient, aged 13, a somewhat delicate-looking little girl, sent to him last February by Dr. Barlow. When

first seen, she had on the back of the left hand three patches (the largest about the size of half-a-crown) of livid desquamating skin; there was also on the back and outside of the same forearm, a little above the wrist, a patch, about two inches long, of dried sero-purulent incrustation, abruptly margined and without any surrounding inflammation. The patient stated that the patches on the back of the hand had had crusts on them. When seen a week later, the condition of the large crusted patch was similar to that of the patches on the back of the hand; but there was, in addition, a patch nearer the elbow as large as half-a-crown, the appearance of which was quite peculiar; it looked precisely as if some mild escharotic had been painted over the surface; for the epidermis was dry, of a buff-brown colour, and commencing to crack at the margins; there was also a halo of congestion round the destroyed epidermis. The diseased part was hot and painful when touched, and the patient complained of a burning sensation in it. Patches continued to come out on different parts of the forearm and arm, later on the left leg and thigh; they did not follow any special nerve-distribution. In April, the patient was admitted to Charing Cross Hospital, and the disease carefully watched. While in the ward, several fresh places appeared in the distribution of the descending branches of the superficial cervical plexus; there were patches over the sternum, left clavicle, and left acromial regions. They commenced as erythematous areas, the coming of which the patient said she could foretell by the pricking and smarting in the part. Subsequently, the epidermis involved turned brown and cracked; next, serum, sero-pus, and often blood, oozed through the cracks and dried on the surface; finally, the crust fell off at the end of about ten days, leaving the part livid and desquamating. At no time was there to be seen any appearance of pustules or vesicles. While the patient was in the hospital, the temperature in both axillæ was taken night and morning. On some occasions, on the affected side it was a degree higher than on the sound side. The spine was tender. There were no other facts of interest in the case to be elicited. The disease seemed to be allied to herpes in its clinical characters, inasmuch as—1. It pursued a definite course; 2. It was associated with pain, such as that experienced in herpes; 3. On one occasion, it followed a special nerve-distribution.

Dr. IRVINE, who had seen the case in the hospital, confirmed Dr. Sangster's description of it. Observation had shown that the skin-affection was not artificially produced.

*Sequel of a Case of Cancer of the Tongue.*—Mr. GEORGE BROWN read a paper on the sequel of a case of cancer supervening on ichthyosis lingue, for which Mr. Brown had removed the patient's tongue in November 1876, as reported in vol. x of the *Society's Transactions*. Seven months after the operation, the stump was attacked with cancerous ulceration, which spread rapidly, notwithstanding the application of various forms of caustic. About six weeks after the ulceration commenced, the case threatened to terminate speedily, as hæmorrhage was beginning to be troublesome. Mr. Brown then ordered an application consisting tannic acid dissolved in alcohol (six drachms to the ounce) to be applied to the ulcerated surface daily. The use of this application had a marked effect in checking the ulceration, and no further hæmorrhage took place, although the patient lived seven months after its use was begun. Mr. Brown believed that the alcoholic solution of tannic acid made as above or saturated (alcohol dissolved nearly an equal weight of pure tannic acid) would prove to be very useful in cancer of the womb, cancerum oris, and ulcerations of a sluggish and unhealthy character generally. In August 1877, the cervical glands, which had been indurated for several months, began to enlarge, giving rise to a good deal of difficulty in swallowing. The patient gradually became weaker, and he died from exhaustion on January 31st, 1878, fourteen months after the tongue was excised. Before death, the glands on both sides of the neck had enlarged to a great size, giving rise to considerable dyspnoea. During the last two months of his life, the patient scarcely took any nourishment but brandy and milk. Freedom from pain was insured by frequent and large doses of morphia.

*A Case in which Gastrostomy was performed for Acute Intestinal Obstruction.*—Mr. CRIPPS read notes of the case. The patient, a thin anæmic boy aged 17, five months ago received a blow on the abdomen, causing intense pain, but from which he quite recovered in a day or two. After this blow, he was much troubled with constipation. Five days before admission into the hospital, whilst bending over, he suddenly experienced intense pain in the right iliac fossa. The next day, vomiting set in, which became fecal on the fourth day. On admission into the hospital, the abdomen was slightly distended, not painful on pressure, the vomiting was almost constant. Injection, inversion, etc., failed to give relief. The patient was then given twenty-five drops of opium and a hot bath. After this, he expressed himself as much relieved. Vomiting entirely ceased, and he slept for several hours; this improvement lasted nearly twenty-four hours, but on the following evening

fecal vomiting set in again more obstinately than ever, and the patient appeared to be sinking. It was then decided to open the abdominal cavity. This was done under carbolic spray, by an incision three inches long in the middle line. The finger introduced into the opening failed to detect any obstruction. The bowel was then gently drawn out from the lower portion of the wound, and passed in again at the upper in such a way that only a few inches were exposed at a time. After several feet of gut had been examined in this way, a portion of the lower part of the ileum was found tightly strangulated, by a fibrous band thrown across from the termination of the ileum to the parietal layer of the peritoneum covering the psoas muscle. The bowel was easily liberated; the abdominal wound was closed, and covered with Lister's dressing. All vomiting ceased, and six hours later the patient had a copious fluid motion. The patient did well for the first few days, when obstinate diarrhoea set in, and he died from exhaustion on the eighth day. There was no rise of temperature or tenderness of the abdomen, and the *post mortem* examination showed no trace of peritonitis. Before admission, the patient had taken large doses of purgative medicine. Attention was drawn to the ease with which the bowel was returned into the abdomen by only drawing out a few inches at a time. It was a matter of regret that opium had been given; and probably this had much to do with the fatal issue. The symptoms at the time were completely smothered by the narcotic; twenty-four precious hours were thus lost, and the operation was ultimately performed upon a patient whose vital energy had slowly sunk below a possible rallying point.

The PRESIDENT thought the case most interesting and well narrated. The surgeon's decision as to the course to be pursued by him in such cases was highly momentous, inasmuch as the patient's condition, unless relieved, tended to death.—Mr. MARSH eulogised Mr. Cripps's method for discovering the seat of the obstruction. Mr. T. Smith had adopted it in a somewhat similar case, and had easily found the obstructed portion of bowel.—Mr. BROWN thought the operation of exploring the peritoneal cavity should be more frequently attempted. It might be done, as he had accomplished it in a case of abdominal tumour without bad result.—The PRESIDENT considered it essential to the performance of the operation to know the nature of the obstruction. All surgeons had seen cases of the kind, and doubted when to interfere; and occasionally the symptoms would rapidly disappear. In a recent case seen by himself, gastrotomy had been strongly advised; but the patient had recovered without it, the administration of opiates and of large enemata having alone been practised. Such cases should make one cautious in proposing this formidable operation.—Mr. CRIPPS replied, and thought the question rested between the dangers of waiting and of operating. Statistics were not ready to hand as to the frequency of recovery when surgical interference was not attempted. In this case, an accident had preceded the obstruction, which Mr. Gay had stated to be the case in one-third of all instances of obstruction.

*Incubative Period of Scarlet Fever and of some other Diseases.*—Dr. MURCHISON read an abstract of a paper upon this subject, based upon observations made in seventy-five cases, and extending over a period of twenty years. Observations upon the incubative periods of small-pox, of varicella, and of measles (about ten days), whooping-cough, typhus fever (supplemental to observation published some years ago in the *St. Thomas's Hospital Reports*), enteric and relapsing fevers, were given, and with the result that in neither of these diseases was the period of incubation fixed. The eruptive fevers in this respect fell, however, into two classes: one class comprised variola, varicella, measles, typhus, enteric fever, relapsing fever, and mumps; these had a long period of incubation; whilst erysipelas, diphtheria, dengue and scarlet fever had a short incubative period. As regards scarlet fever, its period of incubation was variously given as varying from two days to one month. In a paper published by himself in the *Lancet* in 1864, he had analysed twenty-three cases, in none of which did the incubative period exceed one week. The present paper comprised twenty-five cases, in two of which the incubative period was very short; in one, it did not exceed eighteen hours, and, in the other (that of two children on board ship), it was less than twenty-four hours. In the well known case at the West-End, some few years ago, where guests at a dinner-party were subsequently attacked with scarlet fever, in none of them was the incubative period longer than five days. In fact, in none of Dr. Murchison's seventy-five cases was the period longer than six days; in forty-four, it did not exceed four days; in sixteen, it did not exceed two days; and in fifteen cases was not twenty-four hours. Dr. Richardson's personal experience, Trousseau's case, in which the incubation period was seven or eight hours, and other well recorded instances of short incubative periods were given; the result being the rule that if, after exposure to scarlatinal infection, a person were sub-

jected to a week's quarantine, and showed no symptoms of having been infected, he was safe. Dr. Murchison had adopted this rule, and never known it fail. As regarded the point whether it was possible for a patient to communicate an infectious disease during the incubative period, Dr. Murchison gave some instances of small-pox which rendered it probable that such might be the case.—The PRESIDENT thought the paper very important.—Dr. WILBERFORCE SMITH thought it possible there might be varieties of the same contagium, with various periods of development.—Dr. CROCKER mentioned an epidemic of scarlet fever in a children's ward, in which, in most cases, the incubative period lasted about four days, though, in one instance, it seemed to be eight days. In one case of enteric fever, the incubative period had seemed to be only three days.—Mr. G. BROWN mentioned a case of scarlet fever with an apparently conclusive history of incubation, lasting nine days.—Dr. MURCHISON, in reply, thought that differences in the force of the fever depended more upon peculiarities of the patient than upon varieties of the fever-poison. There were many instances on record of very short incubative periods in typhoid fever.

*Sudden Death after the Tapping of a Hydatid of the Liver.*—Mr. BRYANT read notes of this case, which was that of a man aged 40, who for three years had had a steadily enlarging tumour in the right side of his abdomen, which had produced no other symptoms than those caused by its size. It occupied the right hypogastric, epigastric, and lumbar regions, and around the median line of the abdomen for about two inches. On January 21st, 1878, a small trocar and cannula not larger than a silver probe were introduced into the tumour, and nine ounces of clear hydatid fluid drawn off. The puncture was made below the ribs on the right side, and enough fluid was withdrawn to relieve the tension of the cyst, but not to empty it. The operation caused no pain or distress. The cannula was then withdrawn, when in less than a minute the man's face became scarlet, and he was seized with an agonising pain in his jaws. This was succeeded by a death-like pallor, vomiting, stertorous breathing, and death in five minutes. After death, an immense hydatid cyst of the size of a man's head was found beneath the liver, full of fluid slightly blood-stained. The portal vein was in front of the cyst, and the trocar had passed through one of its large branches. The brain and lungs were healthy. The heart on both sides contained uncoagulated purple blood in small quantities, and was healthy. The inferior vena cava was much obstructed by the cyst, and its walls were adherent to a very considerable extent, although there was room for a passage of blood. No opinion was given as to the cause of death in this case, although the symptoms were those of nerve-shock. No air could have entered the blood-vessels through the cannula.

Dr. MURCHISON stated that rapid death after the tapping of hydatid cysts was not unknown in other instances. In a case recently recorded, the patient, who had some peritonitis, lived only eighteen hours after the operation; whilst, in another case, recorded at page 389 of the *London Medical Record* for 1875, by M. Martineau, death resulted within twenty minutes after the operation. In that case, there was no peritonitis.

*A Case of Oesophagotomy.*—Mr. MAC CORMAC read a paper by Dr. McKEOWN of Belfast on this case. The patient, Mrs. G. of Glenarg, in the county Antrim, consulted him on the 16th January last; three weeks previously, she had swallowed a set of false teeth, which stuck in the oesophagus. Various attempts had been made to displace it, but without avail. By palpation, a body could be felt at the lower part of the neck on the right side, and by passing a whalebone with a smooth metallic end down the oesophagus, the diagnosis of the presence of a foreign body was confirmed. The patient being able to swallow sufficient fluid to keep her alive, and the body being just within reach of forceps, Dr. McKeown did not propose oesophagotomy till all other measures had failed. By manipulation on the outside, the body was moved from the right to the left side, and seemed to have been pushed upwards. On two occasions, it had been seized firmly by long strong oesophageal forceps. On the second occasion, most alarming symptoms showed themselves. The plate had been so firmly grasped that it might have been extracted had it been at all possible. The plate could be moved easily from side to side, but when traction was exerted to bring it upwards the patient became livid, respiration seemed to cease, she could not speak, the tongue protruded from the mouth, and the eyes stared. It seemed as if tracheotomy would be necessary, but fortunately, on relaxing the grasp and removing the forceps, all the symptoms quickly abated. All further attempts at extraction by the mouth were definitely abandoned, and oesophagotomy was performed on the 28th January by Dr. McKeown, assisted by Drs. James and John Moore and Dr. Johnston. The incision was made on the left side, and extended along the groove in front of the sterno-mastoid from a point about opposite the middle of the thyroid cartilage to near the sternum. The cervical fascia having been cut, the carotid sheath with its contained vessels

was carefully separated (chiefly by the handle of the scalpel and director, scissors and knife being occasionally used to cut resisting bands of fascia) from the laryngeal muscles, the thyroid body, trachea, and œsophagus. The œsophagus was then opened as freely as possible, but much trouble was experienced in removing the plate, because of its size, its inequalities, and hooks. The plate could neither be moved up nor down, because of the hooks; and it was only by rotating it that it was at last freed and extracted. The plate was found to be situated entirely in the œsophagus at its beginning, the long diameter being vertical. The patient made uninterrupted progress. She was fed for a week by the stomach-pump tube. On the seventh day, the œsophageal wound was healed; and on the fourteenth day the whole wound was closed. The wound was kept scrupulously clean by syringing with solution of Condy's fluid, and also by causing the patient to swallow frequently a little weak whiskey and water with chlorate of potash, so that a part might pass from within outwards whilst the œsophageal wound was open. On leaving town, the patient could swallow quite well, and her speech was quite unimpaired. Dr. McKeown concluded by remarking that, had he known beforehand the shape of the plate, he would not have so long persevered in attempting to extract by the mouth, but should have operated at once. He thought the operation should be more frequently performed than it was. The plate was exhibited to the Society. It had three incisor teeth attached, and a place for a fourth. Its length was an inch and a half.

The President thought the Society much indebted to Dr. McKeown for his valuable paper. He himself had seen three operations of the kind. One was that of a man who had swallowed a piece of bone, and who was under the care of the late Mr. Stanley. After repeated attempts at its extraction by the mouth had failed, œsophagotomy was performed, but too late, for the bone had already perforated the œsophagus, and caused an abscess in the anterior mediastinum, which opened into the pleura. The patient eventually died. In another case, a fish-bone from the œsophagus perforated the aorta.—Mr. BRYANT thought much force should not be used in attempts to extract foreign bodies lodged in the œsophagus; he mentioned a case in which rupture of the œsophagus had been so produced.—Mr. CRIPPS mentioned a case in which a small fish-bone lodged in the gullet. Pain was experienced for a week or so, without other inconvenience. A little while subsequently, there supervened sudden severe pain, a gush of blood from the mouth, and death, which was due to perforation of the œsophagus by the bone, and consequent ulceration of the carotid artery.

## MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Friday, June 21st, 1878.

[SPECIAL REPORT.]

*Medical Act (1858) Amendment (No. 2) Bill.*—On the order of the day for resuming the adjourned debate on the second reading of this Bill, Sir T. ACLAND said: The House is aware that in another place the Government has brought forward a very important Bill affecting the medical profession. That measure has been very thoroughly discussed elsewhere, and I think, before this Bill is read a second time, coming as it does from a private source, the House should know from the Government if they consent to its being read a second time before their own Bill, which stands for a second reading on Monday next. Whether they intend to let the whole matter go before a Select Committee and so delay legislation I do not know, but I hope the leader of the Government will state in what position the House will be if this Bill is read a second time to-night, before the measure introduced by the Government is read a second time.—The CHANCELLOR of the EXCHEQUER: I would appeal to the honourable gentleman the member for Exeter (Mr. Mills) not to press the second reading of this Bill until we have had the Government measure brought before the House. I do not wish to express any opinion at present on this Bill, because I have not given it any careful consideration; but I am aware that it goes into a question of a very important character—that of the construction of the Medical Council—and I think it would be unfortunate if the measure were read a second time before we have that of the Government before us. I would suggest that there should be a further adjournment of the debate. I will move that it be now adjourned.—Mr. MILLS: I should be quite content to act on the suggestion of the right honourable gentleman. I only wish to say, in reference to the remarks that have just been made, that this Bill has now been printed three weeks. Petitions have been presented from more than one hundred medical men, I think, in various parts of the country; it has

the very general support of the medical profession, judging from what is expressed in the medical journals, the accredited organs of the profession. An opinion in favour of this Bill has been expressed by those who attach importance to the one element in this Bill that differs from the Government Bill, namely, the direct representation of the profession on the Council; and a large number of the profession attach importance to this. I certainly shall not withdraw the Bill; on the contrary, I shall persevere with it, not in any sense of hostility to the Government, nor with a desire to delay legislation. I am as anxious for legislation as the honourable member opposite (Sir T. Acland); but what I do desire is that while you are about it you should pass a thoroughly complete Bill. I hope the Government will see fit to embody in their Bill that one condition that does not appear in it—that element that provides for the direct representation of the profession on the Medical Council. My reason for preferring direct representation is not because I have not confidence in the Medical Council, for I have every reason to have confidence in it, but because we have every proof before us that there is difficulty in the way of legislation, and that it would be satisfactory to the profession to have direct representation. If the element proposed to be introduced by my Bill were agreed to by Parliament, I think there can be no doubt that it would strengthen the Council. As to the mode in which the discussion is to be taken, I agree with the Chancellor of the Exchequer that it would be desirable that this Bill should be considered with the Government measure. I will, therefore, put it down for next Monday, for which day I believe the Government Bill stands for second reading. I shall be prepared whenever the Bill comes on to defend the measure so far as it embodies the principle to which I have referred. The Bill is not a party one, as honourable members will see when I state that it has on the back of it the names of the honourable member for Chippenham (Mr. Goldney) and the honourable member for Pontefract (Mr. Childers). As I have already stated, so far as it differs from the Government Bill, it has for its object to strengthen the Medical Council by introducing a provision for the direct representation of the medical profession.—Mr. RAIKES (Chairman of Ways and Means): I would point out to the honourable member who has charge of the Bill and to the Chancellor of the Exchequer, that it will not be satisfactory to the medical profession who are largely interested in this measure, and who greatly prefer it, as I am led to believe, to that of the Government, if it should be made to dance attendance upon the Government Bill at this late period of the session. The other Bill, to which I understand this is not a rival, but rather a supplement, has passed the other House of Parliament; and this is likely, therefore, to be postponed, and come in the wake of other business that has not yet passed the House. I think the honourable member for Exeter would do well to adopt such securities as he can to ensure that his Bill shall be read a second time before we reach the second week of August. It would be undesirable that it should be brought forward at such a time, and that we should not be able to discuss it until the conclusion of the Government measure. The honourable member for Exeter is rather in command of the position as regards legislation on this question, because it will be open to him to raise the question which this Bill is intended to bring before the House on the second reading of the Government Bill by an abstract resolution; and I will ask him whether it would not be a convenient course to take the debate on the main question of direct representation when the Government Bill comes before the House. At any rate, it seems to me that it would be well that the House should have that opportunity of considering the two Bills together, and that they should be discussed at a time when the House is able to give such attention to them that the importance of the matter demands. There is a widespread feeling of dissatisfaction throughout the medical profession—whether it is just or not I do not know—with the Government measure. That it exists, has been abundantly shown by the petitions that have been presented. Before the debate closes, I hope an assurance will be given that there will be an opportunity of raising the questions brought before the House both by this Bill and that the Government have introduced.—Mr. ERRINGTON: Perhaps I may be allowed to say a word or two, as I take great interest in the matter, having had a Bill on the same subject before the House myself. I would suggest to the Chancellor of the Exchequer whether it would not be well to do what the majority of the medical profession desire, and have this intricate question referred to a Select Committee. I do think that the clause which the honourable gentleman the member for Exeter wishes to introduce into the Government Bill can hardly be fairly discussed and introduced at this time of the session. It involves an immense question, and a question which, if settled this year, will be settled for a long time. There is no doubt it would be much more in accordance with the desire of the bulk of the medical profession, if this question were thoroughly thrashed out in committee. It would then receive the attention of the profession in

the autumn, and next year a measure of a satisfactory character might be brought forward.—Sir J. MCKENNA: I would add my voice as strongly as I can in support of the suggestion which has fallen from the honourable member who has just spoken. The measure is one that should not be carried through Parliament at this period of the session, as there are considerable medical interests involved in the matter. The Colleges of Surgeons and Physicians feel strongly on the subject, and I do not think these interests could be legislated for without the parties most interested in the legislation having an opportunity of giving evidence before a Select Committee. I hope the Bill will not be proceeded with, unless it is on that understanding. I do not disguise from myself, or from the House, that the effect of referring the Bill to a Select Committee would be to pass it over for another session; but I think that, as the matter stands, it would be infinitely better that it should be passed over to another session than that we should leave the Colleges of Surgeons and Physicians under the impression that their interests had suffered through the pressing forward of the measure.—The debate was then adjourned.

HOUSE OF LORDS.—Thursday, June 27th.

Dental Practitioners' Bill.—This Bill was read a second time.

## MILITARY AND NAVAL MEDICAL SERVICES.

### PROFESSOR LONGMORE'S INTRODUCTORY LECTURE.

SIR,—I shall be much obliged by your kindly granting me a space in the BRITISH MEDICAL JOURNAL for the following remarks relative to Professor Longmore's Introductory Lecture, delivered at Netley on the 1st instant. Mr. Longmore, in his commendations of the three medical services, begins with that of the Royal Navy. "If," says he to the naval medical cadets, "you have a disposition open to be pleased, you will meet with many pleasant companions; nor in whatever part of the world you may be stationed can you ever be without abundant means of enlarging your views and extending your knowledge. Ships do not remain at sea for long periods, and medical officers of the navy spend much of their time in hospital establishments on shore." These are the professor's recommendations as regards this branch. "Pleasant companions" may, doubtless, be found, and "knowledge" can be acquired in the Royal Navy, but certainly not more easily there than in many other spheres of life and action, so that these points of consideration are by no means special as regards the naval medical service. Then, as to the length of time Her Majesty's ships remain at sea and in foreign parts, "would Professor Longmore be surprised to hear" that four years continuously away from home and family is still no uncommon period of exile for naval medical men. Take, for example, the case of those naval surgeons serving in the South Pacific, on the East Coast of Africa, and in the China Seas. I know the case of a naval medical officer who, out of a total service of, say, thirty years, has been about fifteen years at sea. Perhaps Professor Longmore does not consider these instances of complete severance from "home and hearth" as meriting his description of for "long periods".

"If you have a disposition open to be pleased." What will those fleet-surgeons, ranking with commanders in the navy and with lieutenant-colonels in the army, who in choice of cabins are postponed to junior naval officers, say to this quaintly conditioned utterance of the Netley professor? To be satisfied with such shabby and unjust treatment, their "disposition to be pleased" must be very "open" indeed.

Turning to the Indian Medical Service, the professor pronounces this to be "a magnificent field for the surgeon, whether in its technical, tutorial, or administrative aspects." The technical and tutorial advantages need not dwell on, and may be granted *quantum valent*. But as to the "administrative advantages," Professor Longmore's statement is open to serious comment and easy refutation. Surgeons-general of the Indian Medical Service, whilst ranking with major-generals, receive neither those official marks of respect, nor even the mere pay, due to major-generals. This may seem a somewhat bold assertion, yet it is literally and perfectly true. A major-general proceeding on duty in India receives, at each of the district stations which he inspects, a salute of eleven guns, both on arrival and departure. The surgeon-general of a whole presidency—certainly a not less important or responsible officer—receives not a single gun, nor other becoming acknowledgment of his relative rank and office. To civilians this may seem a small matter to notice, but its significance in the service is real, and is sufficiently and very disagreeably understood and felt. As to pay, will it be believed that, whilst a major-general draws 3,500 rupees *per mensem*, the surgeon-general of the Bengal Medical Service receives only 2,700 rupees, and the other two surgeon-generals of Bombay and Madras have each to be content with 2,000 *per mensem*. That is to say, the surgeon-general of Bengal, Madras, and Bombay are paid at rates which are from twenty-five to twenty-nine per cent. less than the military rank with which theirs corresponds. These are well known and indisputable facts; and, being so, how is it that Mr. Longmore, if aware of such damaging conditions, could declare to his audience that the Indian Medical Service is so "magnificent a field in its administrative aspect"? If not aware of such important facts as these, how can Professor Longmore be considered a safe guide in thus vaunting a service whose highest rank even is neither paid nor respected as it ought to be?

Lastly, Professor Longmore comes, as it were, reluctantly yet valiantly to the discussion of a very ticklish subject—namely, that of the merits of the Army Medical Department as a career for the young surgeon. Here the ground is very rotten; and the profession, being human, naturally takes up the less deceptive standpoints, whilst wisely avoiding the more treacherous. "Many sources of gratification are open to all who join its ranks. You may feel a patriotic pride in belonging to it. Its efficiency has been so persistently decried . . . so much obloquy

has been cast upon the officers at the head of it, that uncertainty and distrust have been propagated far and wide among those who have no personal acquaintance with it. You who have had the courage to come forward in spite of these deterring influences are not likely to regret the step you have taken. In organisation, in the quality of equipment, there is every reason for believing that the medical department will be found far better adapted to meet the demands that will be made upon it than it has ever been at any previous period."

Now, mark: there is not one word in this strange lecture, not even a syllable or hint, as to the grievous maladministration and wrong-doing under which the medical officers of the army now groan. To those who have read, unstudied, "the bare statement," as contained in your issue of the 9th ultimo, and the report of the Irish College of Surgeons just issued, the above remarks of the Netley professor must be exceedingly gratifying and reassuring. In that "bare statement" there were no fewer than fourteen paragraphs of, unfortunately, but too well grounded complaint; and as each and all of these fourteen paragraphs stand unrefuted and irrefragable, but still unredressed, it will be time enough for our zealous professor to "crack up" the medical department of the army as a fair field for youthful medical talent and enterprise when the many wrongs done to those medical officers who are now in the department have one and all been duly rectified.

Professor Longmore, in his friendly feelings towards "those who are at the head of the department," ought not to forget what is due to its seven hundred and odd executive members, so many of whom have done such inestimable service to their country in all parts of the world; and this, too, strange to say, with such peculiar treatment as is described in "the bare statement" already referred to. Equally was the professor bound to avoid misinforming, even unconsciously, the profession in civil life, as to the actual state of this department. No sort or degree of mere organisation, no amount or quality of equipment, can ever suffice, unless there be the requisite complement of able and willing medical officers to work the machine, whether in peace time or in war. As to the present efficiency of these officers, let the recent scandalous breakdown at Woolwich and the Cape bear significant witness. How about said sufficiency in a possibly great and prolonged European war? "Uncertainty and distrust," says the professor, "have been propagated far and wide among those who have no personal acquaintance with the department"; but not nearly so much as among those said seven hundred and odd executive medical officers who, unfortunately for themselves, have had too much "personal acquaintance with it".

Few army surgeons have been so fortunate as Professor Longmore and his friend Sir William Muir. Promoted to administrative rank in 1858, out of their turn, by personal favour alone, each with about sixteen years' service only, and over the heads of a large number of their seniors, many of whom were not less worthy of advancement, those gentlemen may well feel satisfied with a state of things by which they, at all events, were certainly not losers. Neither has Professor Longmore nor the present director-general suffered in any way whatever by the many violations of the celebrated Warrant of October 1st, 1858, because they were promoted before its issue, and none of these unscrupulous infringements have ever affected the administrative ranks of the department. These gentlemen, therefore, never having worn the ill fitting shoe, cannot, of course, be expected to know where and how it pinches; at any rate, so well as those who have been obliged to wear it through so many long and miserable years.

There is one remorseful sort of clause towards the end of the lecture. "I do not mean to say there are no matters connected with the department which one could wish to be different from what they are." An admission which, tardy and vague though it be, is one which, in a fractional degree, saves this introductory lecture of Professor Longmore from the imputation—otherwise well deserved—of being utterly biased and misleading.—Yours very truly.

April 1878.

AND

## POOR-LAW MEDICAL SERVICES.

### SANITARY RESULTS.

MAKING due allowance for the exceptionally favourable meteorological conditions that prevailed last year, the reports on the sanitary condition of our largest English towns during 1877, most of which have now appeared, are full of encouragement to the earnest sanitarian. Few of them are, on the whole, more encouraging than the report for Sheffield, which has recently been issued. Sheffield has not displayed any exceptional zeal in sanitary matters. Indeed, it stands almost alone amongst large towns in having no hospital provision for the isolation and treatment of infectious diseases; neither has it applied the provisions of the Artisans' Dwellings Act of 1875 to those parts of the borough in which extortionate death-tolls are being levied continually. Yet, in spite of this apathy on the part of the Town Council, the Officer of Health of the borough and his sanitary staff have undoubtedly done useful work in recent years, the results of which are plainly evident in the well arranged mortality statistics contained in Dr. Griffiths's last report. It appears that the death-rate in Sheffield in 1877 did not exceed 21.8 per 1,000, which was 5.1 below the average rate in the borough during the preceding sixteen years; this "signifies that 1,435 inhabitants of the borough survived last year who would have died had the death rate equalled the average rate in these sixteen years". The decline in the death-rate in Sheffield has been most marked during the past three years, 1875-6-7, in which the annual death-rate has averaged 23.7 per 1,000, or 3.5 less than the average rate in the preceding fourteen years. The improved sanitary condition of the borough is evidenced as strongly by the decline in the fatality of the principal zymotic diseases and in the rate of infant mortality, as by the general

death-rate from all causes and at all ages. Infant mortality, measured by the proportion of deaths under one year to births, which in the three preceding years had been equal to 188, 176, and 169, further declined last year to 145 per 1,000. It is pointed out, however, that whereas the rate among children born in wedlock did not exceed 138 per 1,000, it was equal to 296 per 1,000 among illegitimate children. Perhaps the most striking feature in Dr. Griffiths's report is the statistics relating to the "unhealthy area" reported upon by him last year, but with which the Town Council shows no signs of dealing. The population of this area in 1877 was enumerated at 23,261 persons, and the death-rate was equal to 35.3 and 35.9 per 1,000, respectively, in 1876 and 1877. The death-rate within this area exceeded the rate in the rest of the Borough by 15.4 per 1,000, signifying "that the lives of no less than 309 persons were sacrificed, during 1877, within this unhealthy area," to its unsatisfactory condition. It is not easy to decide whether, in the report before us, the evidence of necessary sanitary reform is not as strong as that of the undoubted sanitary progress in recent years. Dr. Griffiths's report should, at any rate, secure the zealous support of the Town Council in the realisation of his practical suggestions.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having undergone the necessary examinations, were admitted Licentiate in Dental Surgery at a meeting of the Board of Examiners, on June 25th.

Ackery, John, Camberwell  
Bennett, Frederick Joseph, George Street, Hanover Square  
Burr, Walter, Weymouth  
Fothergill, Edward, Darlington  
Galpin, George Luck, Great Marlborough Street  
Henry, Martin, King William Street, E.C.  
Heplorn, Duncan S., Nottingham  
Keen, Edward, M.R.C.S., Chelsea  
Kennedy, John B., Scarborough  
Newton, J. N. P., Liverpool  
Noble, Charles J., Acton  
Stevenson, Louis, Edinburgh  
Taylor, Arthur, Sutton Coldfield  
Underwood, Arthur S., M.R.C.S., Bedford Square  
Winterbottom, Augustus, F.R.C.S., Sloane Street  
Woodward, Francis H., Princess Terrace, Regent's Park

Eight candidates were rejected.

**APOTHECARIES' HALL.**—The following gentleman passed his examination in the science and practice of medicine, and received a certificate to practise, on Thursday, June 13th, 1878.

Whitehead, George Marsden, Greek Street, Stockport

The following gentlemen also on the same day passed their primary professional examination.

Batty, William Eaton Latham, Liverpool Hospital  
Clowes, Herbert Alfred, Guy's Hospital

The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, June 20th, 1878.

Leigh, William Watkin, Llanfabon, Pontypridd  
Sharples, Charles William, 25, Albert Street, N.W.

The following gentlemen also on the same day passed their primary professional examination.

James, James Thomas, Middlesex Hospital  
Mehta, Masekjee Sorabjee, Bombay

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—At the recent monthly examinations for the Licences of the College, held on Tuesday, Wednesday, and Thursday, June 11th, 12th, and 13th, the following candidates were successful.—For the Licence to Practise Medicine.

Barrington, Frederick Albert  
Beattie, Joseph Aloysius  
Daly, James Nicholas  
Hughes, Richard Lawlor  
Macan, Jameson John

Martyn, Robert Joseph  
Roberts, Frederick Joshua  
Spruille, Simon Davenport  
Vavasseur-Lane, Alfred  
Walley, Thomas Bennett

**For the Licence to Practise Midwifery.**

Barrington, Frederick Albert  
Beattie, Joseph Aloysius  
Bell, Thomas Aloysius  
Dick, James Nicholas  
Hughes, Richard Lawlor

Macan, Jameson John  
Roberts, Frederick Joshua  
Smith, Thomas Orde  
Walley, Thomas Bennett

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—At the examination held on April 24th and following days, the undersigned gentlemen, having passed the several examinations for the second half of the

Letters Testimonial, and having made and subscribed the declaration, were admitted Licentiate of the College.

Banks, Henry  
Bennett, Edward  
Brennan, Henry Arthur  
Carson, Walter Peter  
Denning, Francis Arthur  
Drury, Maurice O'Connor  
Fitzmaurice, Joseph  
Garland, James  
Gibbons, James Barry F.  
Gordon, Robert  
Hawkins, John Sneyd  
Hughes, Richard Lawlor  
Mackie, William James  
M'Munn, John Robert  
Mullen, Vincent French  
Nicolls, Archibald John  
O'Donnell, Thomas Joseph  
Oldham, George St. John  
O'Shaughnessy, Patrick J. B.  
Poole, Walter C. T.  
Philip, Alexander  
Powell, Blacker Castles  
Rundle, Edmund  
Smarrt, Thomas William  
Walley, Thomas Bennett  
Warnock, Robert  
Westropp, Cecil George

## MEDICAL VACANCIES.

The following vacancies are announced:—

**BIRMINGHAM GENERAL HOSPITAL.**—Assistant-Physician. Salary, £100 per annum. Applications to be made on or before the 29th instant.

**BRIGHTON HOSPITAL FOR SICK CHILDREN.**—House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing.

**CLOUGH UNION.**—Medical Officer for Ballygawley Dispensary District. Salary, £100 a year, with £15 as Sanitary Officer, and the usual Registration and Vaccination Fees. Applications to the 1st proximo.

**COUNTY AND COUNTY OF THE BOROUGH OF CARMARTHEN INFIRMARY.**—House-Surgeon. Salary, £125 per annum, with lodging.

**DROGHEDA UNION.**—Medical Officer for St. Peter's East Ward Dispensary District. Salary, £110 per annum as Medical Officer, £20 as Sanitary Officer, with Registration and Vaccination Fees. Personal attendance of candidates necessary on the day of election; viz., the 29th instant.

**GREAT NORTHERN HOSPITAL.**—Surgeon to the Out-Patients' Department. Applications to be made on or before July 2nd.

**HULL GENERAL INFIRMARY.**—Assistant House-Surgeon. Salary, £50 per annum, with board and lodging. Applications on or before July 8th.

**LONDON FEVER HOSPITAL.**—Resident Medical Officer. Salary, £200 per annum, with residence, coals, gas, and attendance.

**MALE LOCK HOSPITAL, Dean Street, Soho.**—House-Surgeon. Salary, £50 per annum, with board and lodging. Applications on or before July 22nd.

**MANCHESTER ROYAL INFIRMARY, DISPENSARY, and LUNATIC HOSPITAL.**—Ophthalmic Surgeon. Applications to be made on or before the 29th instant.

**MIDDLESEX HOSPITAL.**—Assistant-Physician. Applications to be made on or before July 2nd.

**NEWCASTLE-UPON-TYNE BOROUGH LUNATIC ASYLUM.**—Assistant Medical Officer. Salary, £100 per annum, with board and lodging. Applications on or before July 23rd.

**OWENS COLLEGE, Manchester.**—Junior Demonstrator in Anatomy. Salary, £100 per annum. Applications on or before July 15th.

**RAMSGATE AND ST. LAWRENCE ROYAL DISPENSARY AND SEAMEN'S INFIRMARY.**—Resident Medical Officer. Salary, £130 per annum, with furnished apartments, gas, firing, and attendance. Applications to be made on or before July 1st.

**SALFORD AND PENDELTON ROYAL HOSPITAL.**—District Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before July 2nd.

**ST. MARYLEBONE GENERAL DISPENSARY.**—Honorary Physician. Applications to be made on or before July 1st.

**SOUTH DEVON AND EAST CORNWALL HOSPITAL.**—House-Surgeon. Salary, £80 per annum, with board. Applications to be made on or before July 8th.

**WEST BROMWICH DISTRICT HOSPITAL.**—House-Surgeon. Salary, £100 per annum, with board and residence. Applications on or before July 1st.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the announcement.

### BIRTH.

**WHITMARSH.**—On June 27th, at No. 1, Clapton Square, Lower Clapton, the wife of John Lloyd Whitmarsh, L.R.C.P., of a daughter.

### MARRIAGE.

**ROTH—BRIGHT.**—On June 20th, at Wanstead Meeting-house, Leytonstone, Essex, Bernard Roth, F.R.C.S. Eng., eldest son of Dr. Roth, of Wimpole Street, London and Gloucester Place, Brighton, to Lillie, third daughter of the Right Honourable John Bright, M.P., of One Ash, Rochdale.

**THE COLLEGE OF SURGEONS' DINNER.**—At a meeting of the Stewards of the annual festival of the Fellows of the Royal College of Surgeons on Tuesday last, the subject of the election of Chairman was discussed. It was decided to break through the rule heretofore observed, of electing alternately to that post a metropolitan and a provincial Fellow, in consequence of the difficulty of obtaining one of the latter of sufficient standing. On a recent occasion, it will be remembered, they were so fortunate as to secure a gentleman representing the army, and, at the same time, a provincial Fellow, viz., Surgeon-General T. Longmore, C.B., of Netley. As representing the Royal Navy, the Stewards have not yet been able to find one of sufficient standing; they have, accordingly, elected Mr. John Gay to occupy that position in 1879, in succession to Mr. F. Le Gros Clark, who will take the chair on the 4th proximo.

## OPERATION DAYS AT THE HOSPITALS.

**MONDAY.....** Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Royal Orthopaedic, 2 P.M.

**TUESDAY.....** Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

**WEDNESDAY..** St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—King's College, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2.30 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—St. Peter's, 2 P.M.

**THURSDAY....** St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 1.30 P.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.—St. Thomas's (Ophthalmic Department), 4 P.M.—London, 2 P.M.

**FRIDAY .....** Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.—Guy's, 1.30 P.M.

**SATURDAY....** St. Bartholomew's, 1.30 P.M.—King's College, 1 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 1.30 P.M.—Royal Free, 9 A.M. and 2 P.M.—London, 2 P.M.

## MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

**WEDNESDAY.**—Obstetrical Society of London, 3 P.M. Specimens and Microscopic Sections illustrating changes in the Uterus resulting from Pregnancy, by Dr. John Williams. Papers: Dr. John Williams, "On some Changes in the Uterus resulting from Pregnancy, and on their value in the Diagnosis of Parity"; Dr. A. W. Edis, "Case exemplifying the difficulty of Diagnosis in Abdominal Tumours"; Mr. Brewer, "Labour complicated with Ovarian Cyst".

## LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

**CORRESPONDENTS** not answered, are requested to look to the Notices to Correspondents of the following week.

**CORRESPONDENTS**, who wish notice to be taken of their communications, should authenticate them with their names—of course not necessarily for publication.

**AUTHORS** desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL*, are requested to communicate beforehand with the printer, Mr. Thomas Richards, 37, Great Queen Street, W.C.

**PUBLIC HEALTH DEPARTMENT.**—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

**COMMUNICATIONS** respecting editorial matters, should be addressed to the Editor, 37, Great Queen Street, W.C.; those concerning business matters, non-delivery of the *JOURNAL*, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C., London.

**WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.**

**STAFF-SURGEON** and **NEMO**, not having signed the by-laws, will not be allowed to record their votes. They can, however, obtain tickets for the festival on application to the honorary secretary, Mr. B. T. Lowne, F.R.C.S., Colville Gardens, Bayswater.

## A MIDDLE-AGE EXHORTATION TO TEMPERANCE.

A CORRESPONDENT sends us the following interesting quotation from William Langland's *Vision concerning Piers the Plowman* (written about 1360 or 1370).

"And drink when thou druigest; but do hit not out of Resun,  
That thou worthe be worse when thou worche scholdest."

Dreede dilitable drinke; And thou schalt do the better;  
Mesure is Medicine, thann thou much yorne.  
All nis not good to the gost that the bodi lyketh,  
Ne lyfode to the licam, that leof is to the soule."

This may be rendered in modern English as follows.

"And drink when thou art thirsty; but do it not out of reason,  
Lest thou be worse for it when thou shouldst work.  
Dread pleasant drinks; and thou shalt do better.  
Moderation is medicine, though thou desire much.  
All is not good for the spirit that the body liketh,  
Nor sustenance to the body, that is pleasing to the soul."

**SIR**,—Can any of your readers refer me to any medical or other circumstantial account of the death of the Princess Charlotte, or of the case of Lady Flora Hastings—*I am, etc.*,  
GYNÆCOLOGIST.

## QUALIFICATIONS IN THE ARMY AND VOLUNTEER SERVICE.

**SIR**,—Am I right in saying that all medical officers of the army must have a qualification both in medicine and surgery? Is it necessary that a surgeon or medical officer, or assistant-surgeon to a battalion of rifle volunteers, be also doubly qualified?—Your obedient servant,  
VOLUNTEER.

**M.D.**—Can any of your readers recommend any book which describes the treatment of the diseases of advanced life, in a scientific manner, and in accordance with modern pathology?

**NOTICE TO ADVERTISERS.**—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, Twelve o'clock.

## OUR CORRESPONDENT AT ERZEROUH.

OUR readers will be glad to hear that Mr. Casson, our "special correspondent" with Ghazi Moukhtar Pasha's army during the recent campaign in Armenia, whose able letters from head-quarters must be still fresh in the memory of many, has received an autograph letter from that General, unsought for, but expressing his regret at having seen an account of the unfounded charges brought against Mr. Casson by Captain Norman, the *Times* correspondent, in his recently published work on Armenia. Moukhtar Pasha in this letter entirely corroborates our special correspondent's statement, as made before Vice-Chancellor Malins, "that he was strictly fulfilling his duty in leaving Kars", where he had been detained by the grave illness of his colleague, and "attempting to rejoin the Turkish army", to whose head-quarters he was attached. The circumstances under which he rescued his sick colleague were detailed in our special correspondent's letter published on the 29th of December last. This General, moreover, states that he gladly avails himself of this opportunity of bearing his testimony, coupled with a sense of gratitude, to Mr. Casson's brave and faithful discharge of his perilous duties whilst with him in Armenia. Captain Norman can now hardly fail to regret having allowed himself to be misled into the publication of unfounded charges against a professional man who nobly fulfilled duties of great peril, and involving much hardship and self-sacrifice; nor is his position improved by the fact, that he acknowledges obligations for kindly and effectual professional service rendered to himself in a fraternal spirit. The grateful and spontaneous testimony of the Turkish General shines by contrast.

## THE MEDICAL ACTS AMENDMENT BILL.

**SIR**,—If I am correctly informed, one of the clauses of the Duke of Richmond's Medical Bill, if it pass through Parliament in its present form, will prevent licentiates of a college of physicians from using the title of "Doctor", and render them liable to be prosecuted for doing so. This is a very serious matter for those practitioners who for many years past have assumed the title on their door-plates and cards. The question of titles has been discussed in the medical journals times without number, and always with the same result—to leave it an open question; but no one ever thought of a legally qualified and registered practitioner being prosecuted for calling himself "Doctor". If you will publish this note in the *JOURNAL*, it will draw the attention of licentiates to the danger to which they may be exposed, and I hope the Council of the Association will at once direct their attention to the subject. What a triumph for a quack or a prescribing chemist to witness the prosecution of a qualified practitioner while he escapes scot free, so long as he does not call himself "surgeon"!—Your obedient servant,  
ALQUIUS.

## WHO IS A PHYSICIAN?

**SIR**,—In answer to the query by "In Doubt" on the above ever unsatisfactory subject, I would suggest that as a person holding the M.D. degree only could be entitled to be called a "Physician" merely by courtesy, so also courtesy should give to the holder of the F.R.C.P. diploma the right to call himself "Doctor". I took my degree when in America, in the autumn of 1871; but, under present rules, am not permitted to register the M.D. there obtained, though I consider, apart from this, I am fully warranted in calling myself "Doctor", having obtained the fellowship of an honourable and high standing college.—Yours, etc.  
JUNE 22ND, 1878.  
F.R.C.P. EDIN.

## HAY-FEVER.

**SIR**,—Any of your readers who know of any remedy they have found useful for this disease, would confer a favour upon myself and several sufferers whom I have failed to cure after trying all likely remedies, by communicating their knowledge through your pages. As time is just now important, any gentleman who knows of a remedy, and would at once communicate direct with me, would greatly oblige; and I would, after reading, forward his note to your *JOURNAL*.—Yours very truly,  
75, Lever Street, Manchester, June 12/78.  
M.D.

## PURCHASE OF PRACTICE: UNION APPOINTMENTS.

**SIR**,—Will you kindly give me your opinion in your next issue to the following query? I purchase a country practice, with two union districts attached, with the usual clause in the agreement that a sum of money is to be deducted from the purchase money, equivalent to the annual value of such appointments, in case I do not succeed in obtaining them. One district is £60, without extras; the other £37. Are the extras part and parcel of the actual appointments (the yearly value of which is of course uncertain, as they may not return a single shilling, or it may be, several pounds), and to be estimated in the deduction aforementioned?—Yours faithfully,  
JUNE 17TH, 1878.  
A. E.

\* The average annual value of the extras, if it can be agreed, is, we presume, a part of the remuneration for such appointments, which is to be taken in consideration.

## THE MEDICAL ACT AMENDMENT BILL.

**SIR**,—Should the proposed Medical Bill become law, it strikes me that there will be a difficulty in deciding how to style the new diplomates. Probably "Medical Licentiate" would be an appropriate title to give them, and its abbreviation M.L. would not clash with any existing affix that I know of, and, in itself simple, would soon be understood by the public. University graduates will, of course, one and all, object to the new comers styling themselves "M.D." or using the term "Dr."—*I am, etc.*,  
CARLOW, JUNE 10TH, 1878.  
CHAS. McDOWELL, M.D. Dub., F.R.C.S.I.

## CHRYSOPLANIC ACID STAINS.

**SIR**,—On reading Dr. Ogilvie Will's paper on "Chrysoplantic Acid in Psoriasis", contained in your *JOURNAL* of June 14th last, I notice that he mentions, as one of the disadvantages attending its use, the stain it leaves upon the skin after application, and he seems to be of opinion that time is the only remedy to remove this. Allow me to say that, while at one of our metropolitan dispensaries, a similar case came under one of the physicians' notice, of a stain left on a lady's hand, which he fruitlessly tried to remove, till benzole was suggested (as that substance is used to hold the acid in solution during the manufacture), and the results were highly satisfactory. Hoping this remark to be worthy of the notice of the medical profession, I am, sir, yours obediently,  
A. E. WOODS.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

#### ALCOHOLIC DRINKS.

SIR,—Any one studying the current literature of the day on the subject of alcohol cannot help being struck with the absolute laws that are laid down. This is not the way to cope with the evil. We must not make dogmatic assertions—that every glass of whisky or brandy, port or sherry, or even of good beer, which an individual takes is but knocking one nail the more into his coffin. This only weakens our position. The position we, as practitioners of medicine, should take, and take firmly, is moderation. There is no use in preaching the banishment of alcohol altogether to the regions of poisons, placing it on a par with strychnia, arsenic, etc., as we have the experience, of ages, that an ordinary healthy man may take a certain daily quantity with his food without undermining his constitution or shortening his life; and to override this single fact will require proofs stronger than any yet brought forward. If we have no better arguments to make use of than that, because animals only drink water, therefore men should only drink water, we had better be silent. Let us all face this fact, that we cannot, if we wished, hope to abolish the use of alcohol; therefore, let us use our utmost endeavours to keep it within bounds; let the whole weight of our profession be brought to bear against morning drinking, against drinking between meals, and against drinking at any time while the stomach is empty. Let us allow that a glass of beer, a glass or two of wines (even the stronger ones), or a glass of spirits well diluted with water, taken with the midday or evening meal, may be taken for a lifetime without injury by the vast majority; let us even admit that cases have been taken for years without which a few extra glasses of wine after dinner have been taken to meet us half way; and if every medical man throughout the kingdom would do his utmost to prevent the between-meal drinking, or "nipping", as it is called, we should do more good to the community at large than all the rampart teetotal lectures that have ever been delivered. Punch sees this evil, and hits it in his usual happy way. He portrays an octogenarian, who always makes a point of being civil to rich young men whom he sees drinking sherry and smoking cigars just before dinner, as they may then, perhaps, remember him in their wills.

With regard to legislation, let us not waste our time on Permissive Bills or Co-temperance systems, but fight might and main against adulteration. Let us, as a body, impress upon the legislature the great evil that is wrought by this adulteration, and do all we can to get the present laws made more stringent, and to get some competent person appointed in each district to see that they are enforced, and not slurred over as at present.

With regard to alcohol in disease, when and how to use it, let every man use his own judgment in the same way as for any other medicines. If any one imagine that our profession is convinced of its uselessness, and is abolishing its use, let them, as I have lately done, visit in turn our great metropolitan hospitals, and I think it will be found that alcohol, in one form or another, is in more common use than all the other remedies both in and out of the *Pharmacopœia* put together.

In conclusion, let me say that if our profession will concede three points, viz.—1. That moderate quantities of alcoholic drinks may be taken with or immediately after midday or evening meals without acting injuriously; 2. That all alcoholic drinks taken between meals during the morning or while fasting do act injuriously; 3. That of the chief causes of injury to health, especially amongst the lower orders, is the adulteration, which is allowed to pass unheeded—I say that if we, as a body, agree on these three points, and impress our opinion firmly upon the public, or, what is of more importance, get the public to act upon them, we shall have made a great stride in advance.—I am, etc.,

CHAS. F. HUTCHINSON, M.D.

#### BONDS WITH ASSISTANTS.

SIR,—For the information of "Medicus", and those whom he thinks likely to be interested in replies to his inquiries in your issue of the 21st instant, we beg to subjoin answers in juxtaposition with his questions.

Query 1.—What are the precise terms or items in a bond between master and assistant, in which the former binds the latter not to practise after he has ceased employing him?

Answer 1.—A precedent for such a bond may be found at page 401 of Glenn's *Manual of the Law affecting Medical Men*.

Query 2 and 3.—Does it require a lawyer to make the bond every time an assistant is changed? If so, what is the usual charge?

Answer 2.—Anybody may be his own lawyer and draw the bond himself, and so save the guinea charge which a certificated solicitor would make for it. Let, however, such a bold "Medicus" bear in mind the truth of the old adage, which present daily experience illustrates, "The man who is his own lawyer has a fool for his client". But if, in spite of the warning, any such reckless Æsculapius, with the help of Glenn, will run the risk, let him accompany the act by a transfer from one waistcoat pocket to the other of a fee of one guinea, so as effectually to neutralise the sin of cheating the educated professional expert.—Yours faithfully,

SLADDEN, SON, AND TURNER.

42, Bedford Row, W.C., June 15th, 1878.

#### MEDICAL TESTIMONIALS TO QUACK MEDICINES.

SIR.—Surely the use of the name of the late Sir C. Locock in the accompanying advertisement must be an impudent forgery. If so, there must be some way in which such an impostor as his author is can be dealt with and punished. Probably the name of the firm is as much a counterfeit as the other, and intended as a means of trading on another still more illustrious name. It is really time that the whole subject of quack medicines should be taken in hand; and the British Medical Association would be doing good service if it would undertake to move in it.—Yours truly,

F. T. B.

\* The advertisement to which F. T. B. refers is headed "Strength for the weak, and is issued by M. Liebig and Co., 17, Essex Street, Strand, London, and at Paris and New York." It sets forth the merits of "Liebig's Silver Salt" and "Liebig's Pearl of Strength", and contains the following:

"*Next most famous to Charles Locock's, Physician to the Queen.*—I have seen the effect of Liebig's Pearl of Strength, and regard them favourably as a general family medicine, pleasant to take, and beneficial in their action. I have also subjected the Silver Salt to some very severe tests, and find that the hot solution draws out pains and aches in a few minutes, and is, without doubt, the most powerful ingredient at my command, and the two most liebigian to me to fully bear out all that is claimed for them." CHARLES LOCOCK, M.D.

The use of the name of Sir Charles Locock is obviously unauthorised, and the whole advertisement is one which we are surprised to see admitted into respectable papers.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

#### HYPODERMIC INJECTION OF QUININE IN PHTHISIS.

SIR,—I should be glad to be informed as to any experience there may be of the effect of the hypodermic injection of quinine in checking the night-sweating of phthisis. In a patient, male, aged 37, in whom excessive sweating had recurred several times, with high evening temperature (103 deg. Fahr.), and the general state such that I had given up all hope of his recovery—an opinion concurred in by a consulting physician, who saw him—I had used quinine in full doses with marked effect on the temperature; but it had produced such annoyance in the head, that the patient begged to be spared its further administration. I was consequently induced to try the drug hypodermically, being aware that these unpleasant symptoms do not accompany its exhibition in this way. I injected one grain and a half night and morning, and was surprised to find the second evening not only the temperature reduced two degrees, but the onset of the sweating postponed several hours. It has not recurred in the three weeks which have since elapsed. The temperature was fully controlled by the quinine; requiring, however, so much as six grains daily for some days. The amount was gradually lessened, and it is now discontinued, a mixture of three grains three times daily by the mouth being substituted. Not only, too, has the sweating ceased and the temperature moderated, but the patient's state was improved in every particular, except perhaps in the amount of sputa, which is very copious. He is now very cheerful, and has to-day taken half a roast chicken for dinner. A nasty bed sore, which had formed on the right great trochanter, has finally healed.

As my experience is based on but a single case, I should be glad to learn that of others; and if the treatment be new—as it is, so far as I am aware—that it be put to the test by those who have more opportunity. It has acted in my case like a charm, and in all probability has saved a life. I should add that the phthisis, which chiefly affects the apex of the left lung, supervened on an attack of pneumonia (single on the right side) in March last.—I am, etc.,

A. G. B.

DR. JAMES ANDERSON (Ulverstone).—Reports on the *technique* of Sayre's treatment will be found in the recent discussions of the Clinical Society in the JOURNAL, but the most complete account is to be found in Dr. Sayre's book on the subject, published by Smith, Elder, and Co., London.

#### MENSTRUATION OF THE WHALE.

A CORRESPONDENT writes:—The whale Deluga, who died last week at the Aquarium, menstruated so profusely a few days before her death, that the tank in which she was placed had to be emptied twice or thrice on account of the water being contaminated with blood.

T. E. S.—An L.S.A. is at present eligible for the appointment of medical officer of health, without possessing any other qualification.

#### VOLUNTEER SURGEONS.

"DRUM-MAJOR" asks: What is the amount of the government grant to volunteer rifle corps when the acting surgeon to the corps has passed the volunteer medical examination?

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Western Morning News; The Yorkshire Post; The Coventry Herald; The Wisbech Advertiser; The West Briton and Cornwall Advertiser; The League Journal; The Liverpool Daily Post; The Newport and Drayton Advertiser; The Exeter and Plymouth Gazette; The Chicago Times; The Manchester Guardian; The Berkshire Chronicle; The Glasgow Herald; The Oswestry Advertiser; The Edinburgh Daily Courier; The Middlesex County Times; The Liverpool Evening Albion; The Daily Courier; The Kelso Chronicle; The Fifehire Herald; The Merthyr Express; The Carnarvon and Denbigh Herald; The Surrey Advertiser; The Stroud News; etc.

\* We shall be greatly obliged if correspondents forwarding newspapers will kindly mark the passages to which it is desired to direct attention.

#### COMMUNICATIONS, LETTERS, etc., have been received from:—

Dr. J. Burdon Sanderson, London; Mr. T. Spencer Wells, London; Mr. J. Farrar, Morecambe; Mr. W. J. Coulson, London; Dr. J. M. Bennett, Liverpool; Mr. Davy, London; Mr. W. P. Swain, Devonport; Mr. Callender, London; Mr. J. C. Kenton, Glasgow; Justice, Dr. Burgrave, Paris; Dr. A. E. Aust Lawrence, Clifton; M.D., Manchester; Dr. F. A. Pope, Dublin; Our Paris Correspondent; Dr. Pancoast, America; The Registrar of the General Medical Council; Dr. Cole, Bath; Dr. Bushell Anningson, Cambridge; Dr. P. H. Bird, London; Dr. Clifford Allbutt, Leeds; Dr. Prall, West Malling; Dr. de Pietra Santa, Paris; Dr. R. Bruce Low, Helmsley; Dr. Duffield, London; Mr. Alban Doran, London; Mr. J. W. Phillips, Carmarthen; Mr. Balmanno Squire, London; Mr. Grose, Melksham; Dr. Macnaughton Jones, Waterford; The Secretary of the Obstetrical Society; Mr. A. E. Durham, London; The Registrar General of England; Dr. A. S. Taylor, London; Dr. James Gairdner, Crieff; Dr. W. G. Coombs, Winford, Bristol; Dr. Griffiths, Sheffield; Dr. J. Anderson, Ulverstone; Dr. Walker, Peterborough; Mr. Whalley, Bradford; Dr. W. Bird, York; Dr. Lee, London; Dr. Tripe, London; The Registrar General of Ireland; Our Edinburgh Correspondent; Dr. Arthur Edis, London; Dr. John Williams, London; Mr. C. J. Corder, Brighton; Mr. W. H. Wright, Derby; Dr. W. A. Elliston, Ipswich; Mr. William Adams, London; Our Dublin Correspondent; Dr. Lory Marsh, London; Mr. E. Bellamy, London; Mr. Grayson, Sheffield; Dr. Norman Kerr, London; Dr. W. A. Sturge, London; Mr. W. Teevan, London; Mr. Summerhayes, Ramsey, Isle of Man; Mr. T. E. Smith, Stone; Aliquis; Janitor; Dr. Fairlie Clarke, Southborough; Dr. D. Christie, Carrigat; etc.

#### BOOKS, ETC., RECEIVED.

A Practical Treatise on Aural Surgery. By H. Macnaughton Jones, M.D. London; J. and A. Churchill. 1878.
